The behavioural biometrics is a study of such identifying features of a person that are conditioned by the influence of his behaviour, subconscious mind and life experience accumulated unconsciously over the years. The characteristic features are, of course, created by body parts. Currently, Behavioural Forensic Biometrics scientists are using mainly the following:

1. Voice Identification
2. Handwriting/signatures identification
3. Gait Pattern
4. Linguistics
5. Odour Identification
6. Intent discovery/identification

The behavioural characteristics, excluding 1 and 2 are being explored through research and investigation.

Forensic Biometric Elements		
Physiological Biometric Element		
S No.	Biometric Element	Characteristics Used
I	Fingerprints	Ridge Characteristics
2	Iris	Pattern
3	Retina patterns	Vein structures
4	Facial features	Inter-distances of facial features
5	DNA	Inherited code
6	Lip prints	Lip striations
7	Ear print	Outer features of the ear
8	Hand Geometry	Measurements on palm/fingers
9	Vein (hand) Thermometry	Pattern

1. The instrument used is electroencephalograph, the same as used in brain profiling.
2. Instrument used is electrocardiograph.
   Both (1,2) are being investigated for field applications.

Behavioural biometric Element		
1	Voice	Sound spectrographic Traces
2	Signature Handwriting	Writing Characteristics
3	Gait Pattern	Pattern analysis

Biometrics has been in use for identification of human beings over the centuries. The use had been limited but it was increasing over time. However, the need for irrefutable, undeniable and inimitable identity has now, acquired tremendous importance, thanks to computers, the Internet, globalisation of the society/business and migrations of the populations. The computer, the Internet and their siblings (offshoots): online banking/transactions, telemarketing, online cashless business, and increasing crimes like terrorism, bank frauds, narcotics trade, illegal immigration , money laundering, have forced the hands of all governments/business communities and other organisations to adopt Forensic biometrics on large scale to fight the expanding needs. Forensic Biometric, consequently, is occupying the top slot in the identification of the criminal, the one not so criminal and the honest person for the smooth functioning of the society.

22.3 IMPORTANCE

Forensic Biometric system is a system for the identification and segregation of persons. The system of identifications has numerous advantages: it is unique; it is universal, not acceptable to acceptable forgery and it is available in most of the crime situations. The Forensic biometric identification systems are highly utilitarian:

1. Authentication of the person, that he is 'he', is used extensively in security system, banking system and online transactions. It is being used increasingly for:
   - Access control to institution/offices/factories /military installations/buildings
   - Observing a suspect, under surveillance, in a crowd
   - Preparing biometrics data of suspects (terrorist!) and pre-empt their strike.
2. Search for the identity of an unknown person; e.g., a fugitive criminal. The creation of biometric *Portrait Parle* has made the search time/cost-effective. The biometric data of the suspect/culprit is prepared and it is fed into the computer containing the database of the convicted criminals. The computer's matching software compares the data and gives the verdict:

22.3.1 "Match" or "non-match"

3. The identification of a person (criminal) in a crowd is becoming an important application of forensic Biometrics and keeps a watch on his movement throughout. For example, the terrorist, being pursued often mixes up in a crowd. If Biometric data is available it is easy to follow him.

22.4 HANDLING BIOMETRIC EVIDENCE

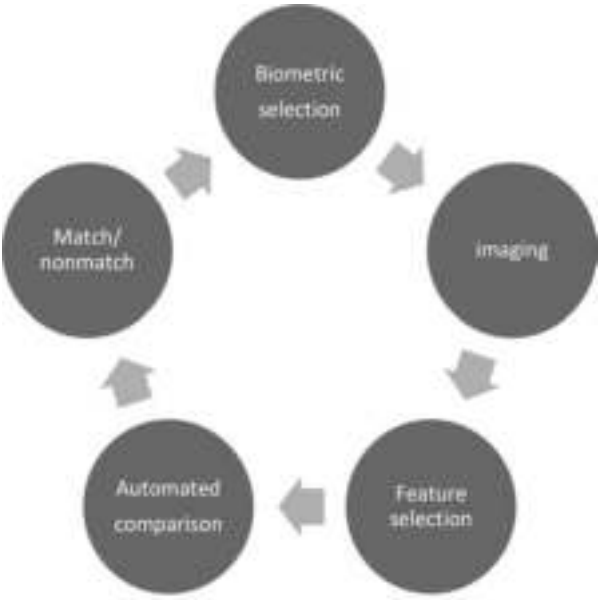

Fig. 22.2
Forensic Biometric Process

The forensic biometrics involves acquisition/editing/storage/retrieval of the biometric data from various sources in digital form. All the processes must be accurate, efficient and secure if the captured data is to provide real Forensic Biometrics service. The process involves the following steps:

22.4.1 Selection of Biometric Entities: Principles

The most important step in using biometrics for forensic purpose is the selection of appropriate biometric entity (trait) because there is no trait, which can fit in all situations. Trait selected should be:

1. Unique
2. Permanent, (like fingerprints, DNA, Retina, Iris)
3. Acquisition savvy
4. Collection/Measurement/recording/extraction savvy
5. Time saver/efficient
6. Accurate
7. Reliable
8. Universal
9. Acceptable to all concerned, and
10. Cost-effective

The forensic biometrics entities have varying number of these qualities, the best being the DNA and fingerprints.

The choice of the trait depends mainly upon the questioned biometric identity. If there are numerous traits that can be used for a particular purpose, then the performance, population coverage, accuracy, convenience, and security (against identity theft, spoofing) aspects decide the choice. The organisational requirements, available equipment and the personal preferences of the expert also affect the choice.

If the Biometrics facility is being created *Ab initio*, (for authentication/identification records), the best items are:

1. Fingerprints
2. DNA
3. Retina
4. Iris

22.4.2 Database

A Database is the collection/storage of the templates of identifying characteristics of individuals from one of their biometrics entities. Some countries have built up huge databases. The most frequently prepared databases are of fingerprints and DNA. Most advanced countries have Fingerprint databases. The data for the database bank follows the following drill:

1. A biometrics reader scans the collectedselected biometrics data for its suitability for database bank.
2. Usually a person oversees the data capture process to ensure integrity.
3. The digital images are thoroughly scrutinised and complete and clear images are selected to extract identifying characteristics.
4. A number of digital images are taken.
5. Software extracts the identifying features and generates a compact yet comprehensive template.
6. The templates are usually stored in central database banks on national /regional bases or on smart cards.
7. It is common practice to prepare more than one templates of the same individual to cater for process variations.
8. The template of an individual is updated frequently

22.4.3 Collection /Capture Drill

The capture process is digital imaging from the various disputed or standard sources. The captured image is then edited to improve the image, enhance its readability/intelligibility and remove the noise. After the processing, the image is framed in a template. The work involves the following sub-steps:

1. The first step in the acquisition of biometric evidence system is to take a digital image to collect/acquire/capture information from the questioned biometric entity in digital form.
2. A digital image of biometric information, corresponding to the questioned entity, is taken from the suspected source(s) through digital photograph or scanning or both.

22.4.4 Identifying data Capture

Fixing/selection/capture of identifying data/traits is the next logical step. It is an important function. High quality and the complete digital image are selected for the extraction of identifying characteristics. A number of clear and important characteristics are selected to create the identifying template for comparison and match. For example, in fingerprints, an adequate number of identifying features like ridge termination/bifurcation/crossing/short ridges/loop formation/gap in the ridges and many more ridge characteristics are captured and used for the identification of the person to whom the print belongs. The position and the orientation of the identifying characters determine its evidential value.

Once the template is ready, it is stored in the computer or in some other similar device (smart cards are used for smaller data bank) and used for comparing/matching the data with authentic/questioned data.

22.4.5 Comparison/Matching process

A matcher (comparator) device is used for matching/comparison. The template carrying data of the unknown person is placed in the comparator, which has template(s) of known person(s). The device compares the identifying characteristics on the new template with the template(s) present there. If the number of matching minutiae is equal to or above the threshold number the identity id declared if it is less than the threshold number, a non-match/non-identity is reported. Thus the matching machine comparison gives identity/non-identity of the person. The results are utilised for required (varied) purposes.

22.4.6 Biometrics Sensors

There are many types of sensors used in biometrics. They vary according to the nature of the biometric entity being studied and the data thereof being collected. The prominent among them are:

1. Fingerprint Recognition.[3]
2. Face Recognition.
3. Iris Recognition.
4. Voice Recognition Sound spectrograph[4]
5. Signature Recognition[5]
6. Retina sensor
7. DNA profiling paraphernalia[6]
8. Brain Electrical waves printing[7]

The details relating to the equipment is beyond the scope of this presentation. The titles of the topics give some ideas about their contents.

3. For details, see the Chapter 5 on *Fingerprints.*
4. For details, see Chapter 29 on *Voice Analysis.*
5. For details, see author's book on *Handwriting Forensics.*
6. For details, see Chapter 21 on *DNA Profiling.*
7. For some details, see Chapter 30 on *Forensic Psychology.*

22.5 INDIVIDUAL BIOMETRIC ELEMENTS

What Forensic Biometrics elements are being used in the identification of individuals? As seen above, any body part and any behavioural trait can be used as an element for biometric forensics. However, some elements are easier to work with than other elements and give better results. Scientists have been researching (and the research continues) on a number of these elements (about 20) are under scrutiny. Here it is proposed to discuss only those that are frequently utilised or are likely to be utilised in the near future; namely:

1. Iris
2. Retina
3. DNA
4. Fingerprints/palm prints
5. Facial features

22.5.1 Iris

22.5.1.1 Nature

The iris is the annular region of the eye bounded by the pupil and the sclera (white of the eye) on either side. The visual texture of the iris is formed during fetal development and stabilises during the first two years of life. Complex iris texture carries very distinctive information useful for personal recognition. The accuracy and speed of currently deployed iris-based recognition systems are promising and point to the feasibility of large-scale identification systems based on iris information. Each iris is distinctive and, like fingerprints, even the irises of identical twins are different. It is extremely difficult to surgically tamper the texture of the iris. Further, it is rather easy to detect artificial irises (e.g., designer contact lenses). Although the early iris-based recognition systems required considerable user participation and were expensive, the newer systems have become more user-friendly and cost-effective.

The iris is a thin, circular structure in the eye, responsible for controlling the diameter and size of the pupil and thus, controlling the amount of light reaching the retina. In the figure below it is the blue area, around the pupil (the circular black spot) in its centre, and white sclera all around. Cornea over the iris is completely transparent. It is, therefore, not visible.

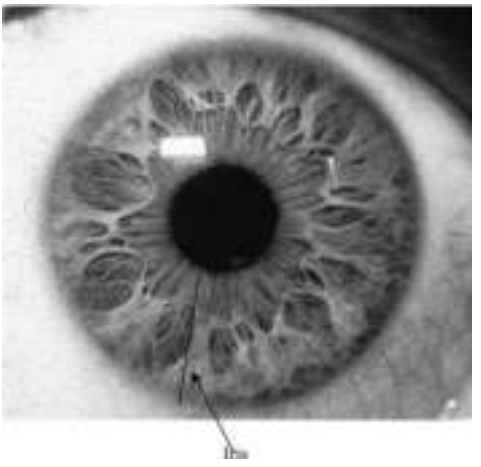

Fig. 22.3

The formation of iris starts at the fetal stage and is complete in about two years after birth when it becomes a permanent biometrics element for each eye. It is unique not only for an individual but it is unique for each eye. Unlike DNA, the iris patterns are different even for identical twins.

The intricate iris structure patterns of each eye of all individuals are distinctive and individualistic. The individuality confers a unique identity to the subject and permits his identification.

22.5.1.2 Ideal identity Feature

The iris is the ideal part of the human body for biometric identification for several reasons including the following:

1) Being an internal body part, it is well protected against accidental/intentional damage or fiddling.
2) Iris is more or less flat. It permits better scanning. Scan can be taken covertly even from a distance, of a few metres.
3) The iris is a random (haphazard) formation during embryonic development. No two identical iris patterns have ever been found, not even in identical twins. The patterns are intricate. They are, therefore, taken as unique[8]. Besides, the formation of these patterns involves so many factors that the chances of duplication are almost next to nil. We have already seen that iris patterns even in two eyes (the left and right eyes) of the same person, or of identical twins (genetically identical persons) are different.

22.5.1.3 Scanning

The iris scanning software has come up, which has almost eliminated the false match (chances $< 1o^{-11}$). Some medical/surgical interventions, sometimes, affect the overall shape of the iris. However, the iris patterns remain unchanged for decades. In one case, an individual was identified even after 30 years through an iris pattern.

22.5.1.4 Advantages

The iris identification offers many advantages:

1. Iris patterns are permanent throughout life.
2. They are unique due to the high complexity of the patterns.
3. They, even from the two eyes of the same person/identical twins, differ.
4. Iris is well-protected internal organ. It cannot be stolen/lost/duplicated/fiddled with.
5. The patterns are easily collected (scanned) and correctly identified.
6. The iris patterns Identification is time/cost-effective.
7. They are amenable for automated use on data from large populations.
8. It is almost impossible to change the iris patterns even by surgery.
9. Fake iris patterns (on designer's contact lenses) are easily exposed/identified.

8. There appears to be no mode (experimental or mathematical) to prove that the iris patterns are unique except that alike patterns have not been found so far. The problem of proof is similar to that of fingerprints!

10. Recent technology has made iris identification-user friendly.
11. Iris pattern can be photographed from a distance even (a few metres).
12. Covert scanning is possible.
13. There are infinite variations in the iris pattern as the creation of the iris is random.
14. Iris patterns can be identified even when the subject is wearing clear contact lenses/spectacles.

22.5.1.5 Disadvantages of the Iris for Identification

1. Small target (1 cm) to acquire from a distance (1 m)
2. Located behind a curved, wet, reflecting surface
3. Obscured by eyelashes, lenses, reflections
4. Partially occluded by eyelids, often drooping
5. Deforms non-elastically as pupil changes the size
6. Illumination should not be visible or bright
7. Some negative (Orwellian) connotations

22.5.2 Retina

Verification/authentication of the identity of an individual through retina biometrics has become one of the most important technologies in Forensics biometrics. The main reasons for its tremendous importance are:

- They are individualistic. Even the identical twins have different retina patterns
- The patterns remain unchanged throughout life. However, eye diseases, diabetes, blood pressures; AIDS bring in changes.
- It is an internal organ and therefore, it not easy to fiddle with its features.

The retina is located on a thin nerve at the back of the eyeballs. The light passing through the eyeballs impinges on the retina to create the vision of the objects from which the light had come.

The capture, analysis and identification, of the pattern of blood vessels on the retina of a person, is fairly tricky. The subject is made to sit close to the lens of the scanner (a special type of camera), asked to gaze directly into the lens, and remain perfectly still and focus on a rotating (revolving) light. The camera, during the process, scans the retina. Any movement can interfere with the process and can require restarting. The process may take about a minute or more. The generated template is one of the smallest (only 96 bytes), of the biometric technologies.

The fact that the retina is small, internal, and difficult to measure, makes capturing its image difficult and cumbersome that has limited its use. Newer time/cost-effective processes are being evolved/explored.

The retina identification mode is highly accurate/reliable. Once its working is streamlined, it is likely to be used more frequently in regulating the entries to important buildings, sites, and installations.

22.5.3 Face

Face recognition is a non-invasive mode. Facial images are probably the most common biometric characteristic for personal recognition. The applications of facial recognition range from a static, controlled "mug-shot" verification to a dynamic, uncontrolled face identification in a cluttered background (e.g., airport). The most popular approaches to face recognition are based on either:

1) the location and shape of facial attributes such as the eyes, eyebrows, nose, lips and chin, and their spatial relationships, or
2) the overall (global) analysis of the face image that represents a face as a weighted combination of a number of canonical faces.

While the verification performance of the face recognition systems that are commercially available is reasonable, they impose many restrictions on the modes of obtaining the facial images. These systems also have difficulty in the identification of a face if the images are taken from two drastically different views or illuminations. For a facial recognition system to work well in practice, it should automatically:

1) detect whether a face is present in the acquired image;
2) locate the face if there is one; and
3) recognise the face from a general viewpoint (i.e., from any pose).

22.5.4 DNA Profiling[9]

DNA (deoxyribonucleic acid) profiling is the ultimate unique code for one's individuality. Only identical twins have identical DNA patterns.

The correct identification of criminals/victims/mental patients/heirs/parentage of children and other individuals has always been one of the most important problems in criminal and civil investigations. The best and certain method had been the identification through fingerprints. This fingerprint identification mode was discovered at the fag end of the nineteenth century. It has been helping the criminal justice system tremendously since then; wherever it was adopted. Now, a similar but a more potent and versatile mode, with far wider ramifications, has been found. It has revolutionised the criminal investigation and trials. It is DNA profiling.

There are two types of DNA, nuclear DNA (nDNA) and mitochondrial DNA (mito DNA). Both are used in the identifications of individuals. However, nuclear DNA is better, with wider applications and specific identifications. The DNA profile of the clue material is compared with that of material from the suspected source to ascertain the identity or non-identity of the common source. If the standard sample s not available from the suspected source, body cells, from his close blood relation(s) can provide the DNA profile for comparison. Further, mitochondrial DNA from hair and bone, where nuclear DNA is not available, can be used for the identification.

The identification *via* DNA profiling is superior to other methods of identification in many respects.

22.5.5 Fingerprints

Fingerprints for biometric identification have assumed great importance in recent times. It is used extensively in the security system, banking system, online transactions and for access control to institution/offices/factories /military installations/buildings.

9. For details see chapter on 'DNA Profiling'

A fingerprint is the pattern of ridges and valleys on the surface of a fingertip, the formation of which is determined during the first seven months of fetal development. Fingerprints of identical twins are different and so are the prints on each finger of the same person. It is possible to embed fingerprint-based biometric in a laptop computer. The accuracy of the currently available fingerprint recognition systems is adequate for verification systems and small- to medium-scale identification systems involving a few hundred users. Multiple fingerprints of a person provide additional information to allow for large-scale recognition involving millions of identities. One problem with the current fingerprint recognition systems is that they require a large number of computational resources, especially when operating in the identification mode. Automatic identification is sometimes hindered because of genetic factors, ageing, environmental, or occupational reasons (e.g., manual workers may have a large number of cuts and bruises on their fingerprints that keep changing).

22.5.6 Gait[10]

Gait pattern is the walking picture of an individual. It is a complex spatio-temporal biometric. It has been utilised in the identification of criminal when they are caught in the CCTV.

Gait pattern is not very distinctive, but is sufficiently discriminatory and can indicate the possible person. In India, khojis[11] have used to help apprehend criminal from gait pattern marks.

Gait pattern is a behavioural biometric. It changes over a long period, due to fluctuations in body weight, major injuries involving joints or brain, or due to inebriety.

Gait pattern acquisition is an acceptable biometric. It is mainly evaluated from video-sequence footage of a walking person. Several different movements of each articulate joint are studied and evaluated.

22.5.7 Ear

The shape of the ear and the structure of the cartilaginous tissue of the pina are highly individualistic. The ear recognition approaches are based on recording the distance of salient points on the pinna from a landmark location on the ear. The features of an ear are very distinctive but the images often defy individualisation of the identity of the person.

22.5.8 Signature

The way a person writes and the way he writes his signatures are known to be a highly characteristic, individualistic in most of the cases of writers. They have been accepted in government, legal, and commercial transactions as a method of identification of the signatory.

Signatures are a behavioural biometric that change over time and are influenced by physical and emotional conditions of the signatories.

No person can write his signatures exactly alike twice even when he writes the two signatures one after the other. The variations, however, are of minor and within limits. They do not interfere in the identification of the writer unless master forger has reproduced the signatures.

10. For details, see Chapter 6 on Track Marks.
11. Tracker worked in North-West, India.

Handwritten signature authentications are of two types:

1. Signature verification and
2. Signature identification

The signature verification system decides if a given signature belongs to a person who professes that they are his signatures. Signature authentication can be static or dynamic. In the static mode (referred to as off-line), only the digital image of the signature is available. In the dynamic mode, also called "on-line", a graphic tablet acquires the signature's data by means of or a pen-sensitive computer display. Data includes measurements of parameters of pressure, acceleration, speed, rhythm, and movements.

Specific software extracts the features from the signatures, compares the extracted features in both static and dynamic signatures, and decides whether the signatures have been written by one person or not.

22.5.9 Voice

Both physiological and behavioural biometrics influence voice. The voice characteristics are determined by the shape and size of the appendages: vocal tracts, mouth, nasal cavities, and lips. The characteristics of human speech change over time due to age, health conditions, and emotional state of mind.

Voice identification has been used extensively in Forensics for a long time. It is not very distinctive and not appropriate for large-scale identifications. It is however, being adopted for biometric forensics.

A text-dependent voice recognition system is used for the identification of the voice uttered in a predetermined phrase.

A text-independent voice recognition system also exists, which is more difficult to design but offers more protection against fraud.

A distinct disadvantage of voice-based recognition is that speech features are sensitive to a number of factors such as background noise, attempted disguise.

Speaker recognition is most appropriate in phone-based applications, but the voice signal over the phone is typically degraded in quality by the microphone and the communication channel.

22.5.10 Biometric Intent

In recent times, new biometrics, called biometrics of intent based on brain (electroencephalogram) and heart (electrocardiogram) signals is coming up. It aims to scan *intent.*

The research has shown that people have certain distinct specific brain and heart patterns. The patterns permit the identification of individuals. The technology is fraud-resistant.

The technologies are cumbersome and of low accuracy at this stage of development.

The researchers in Forensic biometrics are also analysing physiological features such as eye movement, body temperature, breathing, and predict dangerous behaviour or hostile intent before it materialises into action.

22.6 CONCLUSION

To sum up, each biometric technique is admissible and there is no optimal biometric characteristic. For example, it is well known that both the fingerprint-based and iris-based techniques are more accurate than the voice-based techniques. However, in a telebanking application, the voice-based technique may be preferred since it can be integrated seamlessly into the existing telephone system. However, a forensic biometric identification method needs to be:

1. Logical, balanced, robust,
2. Validated, verifiable and infallible
3. Provide strong supporting data for the findings
4. Provide reliable results in forensic conditions
5. Provide the range and limits of use of the method

23.1 INTRODUCTION

Death investigation is the most important assignment given to an investigating officer, as murder is the most heinous crime. It needs skill, experience, intelligence and the ability to win the confidence of persons to get information and cooperation from them.

All sudden deaths are not murders, accidents or suicides. In fact, in the UK they have calculated that about 80% of sudden deaths are natural deaths (act of God). Only about 20% of deaths are unnatural — suicide, accidents or murders.

There is an old saying that "dead man tells no tales." It is no longer true. A corpse, in competent hands, helps to establish:

- *Corpus delicti*
- His identity
- The time of death
- The cause of death

- The *modus operandi,* and
- Linkage, through clues, of the culprit the victim, the scene, the weapon of offence and other paraphernalia involved in the crime.

The investigation of death involves a multi-pronged approach:

23.1.1 Examination of the Scene

Examination of the scene of occurrence is an important step in the investigation of death. The general aspects of the examination of the scene have already been discussed.[1] The chapter has covered Proper protection, detailed documentation (videography, photography, sketching, textual description, search, collection, preservation, and despatch of evidentiary clues) and reconstruction of the occurrence. Here we discuss death investigation specific aspect only:

23.1.2 Indoor Scene

The IO pays special attention to the following aspects of the indoor crime scene:

1) **Suicide note;** it may be real or fake. In about one-third cases the person committing suicide leaves a suicide note.
2) **Hiding places**; most of the criminals, if they have the time, they hide the incriminating objects including the weapon of offence, discarded garments, materials used for wiping stains. The IO identifies the places and seizes the hidden objects. They carry vital evidence, even fingerprints.
3) **Conditions of the premises**; doors, windows, lighting, heating, fireplaces, dustbins, waste heaps, and nearby vacant spaces are examined. Documents, garments, and other clues may have been burnt/thrown/buried. Residual fragments may still be available.

   Kitchens, bathrooms, toilets may give useful indication and presence of washed blood. Towels may carry bloodstains. There may be even fingerprints on taps and washbasins.

   Walls, ceiling, windows, and ventilators may carry bullet damage or marks in cases of shooting. They are located and documented. If bullets are found embedded, they are extracted carefully to avoid further damage.

   Ashtrays, waste paper baskets, waste heaps, and dumps are searched for incriminating clues.

If there is evidence of eating or drinking, remnants of the food/drink and their containers are carefully collected and processed for incriminatory evidence.

23.1.3 Outdoor Scene

In the examination of outdoor scenes the IO pays attention to:

1) Protect the scene from the curiosity hunters and the involved criminal or their sympathisers. Only the investigator(s) should enter the scenes. He:
   - Cordons off the concerned area.
   - Formulates a plan for examination of the scene.
   - Employs minimum persons to search the scene.
   - Examines the scene during the day, if possible. Otherwise, he uses floodlights.

1. See discussion in chapter 4 on Scene of Occurrence.

2) Process the scene the earliest. Delay destroys evidence. Dust storm, rain, floods, and traffic are potential destroyers. In addition, interested men can and do damage the evidence.
3) Record the disturbed foliage. It may indicate the path of the fugitive, the flight of bullet/missiles/objects, hiding place of a weapon of offence.
4) Preserve/protect biological evidence (skin, flesh, and blood, hair) to prevent destruction/putrefaction/contamination; or, displacement by beasts.

23.1.4 Signs of Struggle

Scrutinise the scene for signs of a struggle:

1. Upturned furniture,
2. Splattered blood,
3. Pulled out hair,
4. Marks of weapon of offence at the scene: doors, walls, furniture,
5. Foot or footwear marks on floors, furniture, bed,
6. Foreign material like bullets, cartridges, cartridge cases, fragments of weapon of offence, powder residues,
7. Defence injuries on the person of the deceased.

23.1.5 Real or Fake Scene

The following factors indicate the fake scene:

1. The quantity of blood at the scene *vis-a-vis* the extent of the injuries is less.
2. Nature, position, size, direction of stains of other body fluids especially semen, saliva, urine and faeces, does not correspond with the given facts.
3. The version(s) of the occurrence is incompatible with the condition/disposition of clothes: state of buttons, tears, displacement, abrasion, creasing, staining.
4. The evidence: blood, bullets, cartridge cases, semen, and other items, underneath the body; may falsify the given version.

23.1.6 Side Information

IO collects side information:

1. Who was the victim?
2. Who saw him alive last?
3. Who was to meet the victim?
4. Who would gain by his death?
5. Who would lose by his death?
6. How much money did the victim carry on his person at the time of death?
7. What was the victim doing when he met his end?
8. What does the psychological autopsy of the victim indicate?
    - Depressed?
    - Stressed?

- Suicidal tendencies?
- Moody?
- Eccentric?

9. Was the victim drunk or under the influence of drug(s)?
10. Who found the victim? Relations or friends or business associates?

23.1.7 Examination of the dead

Examination of the corpse at the scene is done routinely. The investigator officer prepares the inquest report. It must be thorough. However, it should be limited to external examination only. A medico-legal expert does a detailed examination in a post-mortem examination.

The investigating officer should:

1. Confirm death.
2. Photograph the body "as is, where is".
3. Sketch the position of the body.
4. Record the description of the body, the position of the body *vis-a-vis* other articles at thescene. Describe the body fully: head, trunk, arms, and legs. He takes special care to describe the position/condition of the head, mouth, eyes.
5. Record the injuries carefully. Figure out the nature of the weapon of offence.
6. Record the bloodstains on and around the body without disturbing the body: their size, position, direction.
7. Record if there is blood froth (blood mixed with saliva and air). Usually, it occurs when blood enters into air passage while the person is still alive. But in some cases putrefaction may give out froth.
8. Estimate the quantity of blood at the scene. Is it consistent with the injuries?
9. Note the number, size, nature and position of other stains.
10. Record the condition of the clothes of the victim.
11. Outline the position of the body with chalk before removal.
12. Place the dead body in a clean white, plastic sheet for its transfer to the mortuary.

23.2 POST-MORTEM EXAMINATION

Post-mortem examination of the dead, in cases of a sudden and suspicious death, is done in all cases routinely. It has great value. The IO participates actively. He should:

- Remain present at the time of post-mortem examination.
- Ensure collection of all evidentiary clues.
- Get the body (clothed as well as naked) photographed to preserve the evidence on the person of the deceased. Colour photography is superior to record the nature and extent of injuries. Obtain close up photographs of the injuries and other evidence on the person of the deceased
- Collect clothes invariably. They should be properly marked for identity.
- Collect relevant samples of blood, hairs, fingerprints, and viscera if required.

The government medical officers working as medical practitioners do the post-mortem examination and other medico-legal work, in India. Specialists in the field are available only in metropolitan cities or in medical colleges. Most of the doctors elsewhere do not possess the necessary expertise in the medico-legal work. They are unable to do justice to this important work. The cause of justice suffers. There is, however, increasing realisation of the lacunae and efforts are being made to take remedial measures.

23.2.1 Importance

The post-mortem examination provides important evidence relating to death. It helps to:

1. Fix the *corpus delicti* and the cause of death.
2. Ascertain if it is Suicide? Accident? Homicide? Or, killing in Self-defence?
3. Indicate the weapon of offence: (firearm, sharp-edged weapon, blunt weapon).
4. Give the number of injuries and *inter alia* the number of weapon(s) or the number of assailants, under favourable circumstances.
5. Determine the sequence of events of the incident.
6. Determine the evidence of other crime (sexual assault), if any.
7. Confirm/discard a given version or provide a new version of the occurrence.
8. Provide identification data on the victim, in the case of an unidentified body.
9. Collect evidentiary clues: foreign matter, glass pieces, part of broken weapon, projectiles, GSR.
10. Collect viscera, blood, urine, other body fluids, hairs, nails, bones for further investigations.
11. Determine the serious nature (fatal or non-fatal) of injuries.

In short, post-mortem examination helps the criminal justice system to establish the *corpus delicti*, the *modus operandi*, the sequence of events and to locate, collect and preserve clues to link the criminal with the crime, with the crime scene and with the victim *inter se*!

23.2.2 Basic Steps

The basic steps in proper post-mortem examination in death cases are to:

1. Take photographs of the deceased before the examination, during an examination, and after the examination. The facial features, other identification marks (tattoo marks, any deformity,) are photographed. They help to identify the deceased, especially in the identification of unidentified and excessively putrefied or mutilated bodies.
2. Obtain the case history.
3. Visit the scene of occurrence whenever possible. Otherwise, understand the scene through video film, photographs, sketches and textual description of the investigating officer.
4. Carry out the post-mortem examination in the mortuary only.
5. Ensure no fingerprinting or embalming is done before the post-mortem examination. Important trace evidence can get lost and the artefacts introduced. They mislead.

6. Ensure the collection and protection of the trace evidence (GSR, paint, smears, stains, hair, fibres, dust and other traces.) while transporting the body to the mortuary.
7. If the hand(s) of the victim bear evidence: hair, fibres, glass pieces, stains or other traces cover the hand with clean paper or preferably with a clean plastic cover.
8. X-ray the body (relevant body parts) before starting dissection for locating any foreign bodies or fractures.
9. Photograph all the injuries (abrasion, contusions, punctured or incised wounds) before and after cleaning them, along with a scale and identity chit.
10. Ensure that medico-legal expert himself take off the clothes from the person of the deceased.
11. Examine the clothes as part of the post-mortem examination. Ensure their identity through identification marks.
12. Recover all evidentiary clues, on the person of the deceased.
13. Use simple terminology even when discussing technical aspects of the evidence.
14. Record the negative evidence also. It may look apparently inconsistent with the main findings but later may prove invaluable.

23.2.3 Examination

A post-mortem examination in a murder case provides sufficient evidence to link the criminal with the crime. The steps involved in the examination are:—

23.2.3.1 General examination

- Fix the age, sex, race, body build, and height.
- Describe any deformities, oddities, scars, old injuries, tattoo marks, moles.
- Describe clothes: their number, nature and the evidence (tears, holes, stains, smears) thereon.
- Link the holes, tears, abrasion on the clothes with the injuries on the person of the deceased.
- Locate collect and preserve all the evidence found on the person of the deceased including that found on the clothes.
- Pack them only after drying, if they are wet.

23.2.3.2 Body examination

- Observe and describe the degree and extent of lividity and *rigor mortis* found in the body or in part of the body thereof, if any.
- Observe and describe any oddity on any part of the body.
- Observe and describe signs of asphyxia, if any.
- Describe dental/denture condition.
- Describe the existence of any disease, surgical intervention, which could have contributed to the death of the deceased.

- Locate any defence injuries.
- Record all the negative (inconsistent with the main hypothesis) evidence also.

23.2.3.3 Handling injuries

- Observe and record all the major or minor, internal or the external injuries.
- Observe and evaluate a firearm injury from the site of entrance and describe the wound of entrance, the internal track and the lodgment site or the exit wound in detail. Give serial numbers to each injury.

The description should contain (whenever possible):

(a) The possible nature of the weapon
(b) The presence or the absence of the GSR
(c) The direction of fire, with deflection, if any
(d) The condition of the projectile: Whole? Deformed? Fragmented?
(e) The presence or the absence of any extraneous matter on the projectile from the intermediate target or from the ricocheting surface
(f) Describe site(s) of the injury without using medical terminology

23.2.3.4 Documentation

Log all collected information through:

(a) Photographs
(b) Sketches
(c) Exhaustive description
(d) X-rays, for bone damage

Note.—the evidence on clothes of the victim is logged in the same way.

23.2.3.5 Internal examination

Internal examination involves checking of all the major body organs, cavities, bones for injuries, the extent of damage, decapitation, defects. The examination should be systematic and properly documented. Usually, the departments have forms prescribed for recording the observations. The body parts, observed invariably, are:

- Head
- Neck
- Respiratory system
- Cardiovascular system
- Gastrointestinal system
- Reproductive system
- Urinary tract
- Panaceas, spleen, adrenals, biliary tract

These organs are examined not only for injuries but also for any abnormality or disease. If nothing abnormal is noticed, their absence is recorded. Usually, the letter NAD (Nothing Abnormal Detected) is used for the purpose.

23.2.4 Toxicological Material

In cases of deaths where the cause of death is properly established, the toxicological examination is not necessary. However, in certain cases where the cause of death appears fake, to divert the attention of the authorities or where no other definite cause of death is established, materials for toxicological examination is collected. As a matter of routine the following materials are collected and preserved:

- **Clothes**
- **Stains**, if any.
- **Blood**: it is the most important autopsy material. About 500 ml blood is collected from artery/vein/heart.
- **Urine**; it is the second best toxicological material collected in an autopsy. The total amount of urine in the bladder is collected.
- Vitreous fluids.
- Stomach contents: Whole
- Intestines with contents 30 cm
- Liver containing gall bladder with its contents 100 g
- Kidneys Half of each kidney
- Spleen Half in adult and whole in children
- Bile
- Lung (in cases of volatile poisons) Tied at the open end

The following materials are also helpful:

1. Brain Whole
2. Lung One
3. Heart Whole
4. Muscles 500 g
5. Bone 500 g
6. Hair and nails 10 g
7. Bones, Shaft of femur bone and nails are useful for chronic metal poisoning.
8. Lung, heart and brain are helpful for gaseous and volatile poisons.
9. Muscles prove useful in acute poisoning cases where the body is extensively putrefied. Muscles are resistant to putrefaction and are not easily decomposed.

   Hairs have acquired tremendous importance as a clue source not only for DNA profiling but they are used extensively for identification of drug addicts and alcoholics.

23.2.5 The Opinion

The opinion of the medico-legal expert is the brief conclusion of the observations and inferences. It contains the main information:

- Cause of death
- Mode of death
- Time of death

The medico-legal expert may have to supply additional information on demand.

23.2.6 Post-mortem Report (PMR)

The post-mortem findings are not only important to the prosecution but they are equally important for real justice delivery. The post-mortem report is written on a standard comprehensive form. However, the expert furnishes additional information/clarifications on demand.

There is ample scope to improve the PMRs. A Better description, better illustrations, and more photographs and less use of technical terms can go a long way to make the PMRs common man savvy. The coming up trend to prepare a video clip should prove of immense help.

23.3 MURDER, SUICIDE OR ACCIDENT

The criminals often try to dub a murder as suicidal or accidental death. To identify the nature of death, therefore, is an important medico-legal problem. The expert has to study the total evidence, which includes:

- Examination of the crime scene,
- PMR of the body,
- Signs of struggle at the scene, on the person of the deceased; or, on the body of the culprit,
- Eyewitness accounts,
- Nature of the weapon(s) used,
- Video-film, photographs, sketches and textual description of the occurrence and of the scene,
- Side information, if any.

23.3.1 Homicide

The following evidence indicates homicide.

1. Attempt to hide the corpse
2. Attempt to dispose of the body
3. Absconding of the suspects
4. Manipulation of physical evidence to make it look like a suicide or accident
5. Absence of weapon of offence
6. Creation of fake scene
7. Motive: financial gains, enmity, rivalry or land disputes
8. presence of non-accidental/non-self-inflicted injuries.
9. Presence of self-defence injuries

23.3.2 Suicide

Fig. 23.2

Position of weapon and other articles vis-a-vis the victim in a suicide case can ofIten reveal whether the suicide is real or fake. In this case the facts (firearm in hand without cadaveric spasm) location of bullet and blood inside a rolled carpet went against the theory of suicide

The following evidence indicates suicide:

1. **Genuine suicide note**; about one-third persons committing suicide leave suicide notes.
2. **Previous attempts**; at suicide indicate suicidal tendencies.
3. **Extreme depression;** due to physical pain (illness), emotional problems, fear, quarrel, financial loss may lead to suicide.
4. Certain sites are predominantly used by suicides for self-inflicted injuries. For example, with firearm, temple, forehead, mouth and chest are the favourite sites. With knife cutting of throat and wrist are the favourite sites. Hesitation injuries are also observed in some suicide cases.
5. The person may use more than one method to commit suicide. For example, when a suicide fails to use a knife successfully, he may succeed to hang himself to death.
6. Certain modes of suicides are favoured. Usually, they are less painful and easily accomplished. For example, hanging, sleeping drugs, opium, are quite frequently used.
7. Presence of weapon at the prone position may suggest suicide.

23.3.3 Accident

The following points indicate accident:

1. The source and cause of the accident should be near the victim
2. Death not due to suicide/homicide
3. Tell-tale physical evidence at the scene or with the victim
4. Absence of natural cause: disease, Act of God and the like
5. Absence of struggle/violence
6. Absence of defence injuries

23.4 IDENTIFICATION OF DEATH

What is death? Death is the cessation of life. Life in an individual is sustained by the functioning of the brain, heart, and lungs. If these three body parts stop functioning, the person dies a somatic death. The body parts take some time to become inactive. When they become inactive, the person is said to suffer 'molecular' death.

In most of the cases, identification of death offers no problem, for example, when the head is found severed from the body, death has undoubtedly taken place. However, in some breathing/heartbeat become too feeble and mislead. For example, drugged persons, drowned persons, persons suffering from electric shock or snake-bitten persons may give the impression of death. One has to be cautious. In all such cases, a medical officer must check the victim. The following signs guide n most of the cases:

1. ***Breathing.***—The clouding of a mirror placed before the mouth-nose of the victim, may indicate life.
2. ***Pulse.***—Pulse detection is a sure sign of life. However, the converse is not true. Non-detection of pulse even for half an hour may not mean death.
3. ***Eyes.***—The eyes should react to strong light. On death circulation of fluid stops, tension of the eye muscle is lost and clouding of the cornea appears.
4. **Strong painful stimuli**; they make the muscles of a live person twitch but not that of a dead person.
5. ***Plasticity of body tissues.***— The skin, flesh, lose elasticity and tension. On pressing, flattening take place.
6. **Incised wounds**; they do not gape on dead bodies.
7. **Brain Death**; artificial respiration and other means to prolong life have added a new dimension to the concept of death. When does a man die? When a person fails to respond to the above mentioned tests, he can be considered dead for all practical purposes. But under external stimuli, a person may respond to some of the above tests and yet he may be dead. The death, therefore, is identified when the brain stops activity. The brain remains active even when a person is sleeping or unconscious. The activity stops only when he dies.

   The brain activity is detected by a machine called Electroencephalograph (EEG). If the brain remains inactive for a number of hours (6 hours), the subject is considered/ declared dead.

   Another sure test is to check the circulation of fluids in the brain (cerebral circulation) by injecting radioactive isotope-tagged chemical. If the brain shows no circulation for ten minutes, the subject is dead.

8. **Other Signs of Death;** they include:
   - ***Cooling of the body.***—Body soon after the death cools down and acquires the temperature of the surroundings.
   - ***Lividity.***—Due to non-circulation, the blood accumulates in the lower parts of the body (which are nearest to the earth), giving staining to those parts. – The phenomenon is called lividity.
   - Rigor mortis.—It is the stiffening of the body after death. It starts soon after death (about 4 hours) and continues for a considerable period.
   - ***Putrefaction.***—The bacterial growth in humid and hot climate starts putrefaction of the body. It is the sure sign of death, but it is too belated to be of any forensic significance to identify death.
   - ***Miscellaneous.***—Mummification, adipocere formation, skeletal formation are signs which appear only after long periods.

23.5 TIME OF DEATH

The determination of the time of death is seldom accurate and therefore, never reliable. It may help in some cases, but in others, it can mislead.

> *In a case of death of an infant, the body was found floating in a plastic bag in the sea. Post-mortem examination gave the idea that the body of the infant was in water for 2-3 weeks. Later investigations revealed that the body was in water for 24 hours only. It had been kept in lye previously. (CH)*

Various changes take place in the body. They help to estimate the time of death. These changes depend upon the following general factors:

1. Temperature,
2. Humidity,
3. Supply of oxygen,
4. The state of health,
5. The cause of death,
6. Environments.

As can be imagined, these conditions vary widely in each case. The estimate of time of death, therefore, can always be a rough estimate at best.

Dogmatic assertions of the time of death should neither be expected from seasoned experts nor accepted. However, the following changes in the body indicate the time of death.

23.5.1 Cooling of Body

A lot of work has been done to determine the time of the cooling of the body from normal (rectal) temperature (98.6°F) to the temperature of the surroundings. A large number of formulas have been given, a simple one is:

$$T_e = \frac{T_b - T_r}{R}$$

T_e = Time elapsed since death
T_b = Normal body temperature (98.6 F) or (37°C)
T_r = Temperature of rectum (O_F or O_C)
R = Rate of fall of temperature per hour

23.5.2 Chemical Changes

A number of chemical changes have been studied. For example, variations of potassium content, ascorbic acid, succinic dehydrogenase have been studied. However, the inconsistency of the results does not permit proper estimation of the time.

23.5.3 Lividity

Livid stains appear on the lower parts of the body in 0.5 to 2 hours after death and are completely developed in 6 to 12 hours. Lividity is hastened by lingering deaths.

If the body position is changed frequently, lividity does not develop.

23.5.4 *Rigor Mortis*

Stiffening of the body in most of the cases starts after about 4 hours and is completed in about 8 hours. In some cases, it may take even up to 15 hours to complete.

Cold and poisons delay the appearance of *rigor mortis* (Examples, arsenic, mercuric chloride).

High pressure, temperature, certain alkaloid poisons (example: Strychnine) and certain diseases hasten the onset of *rigor mortis*.

The *rigor mortis* wears off in about 36 hours, though in some cases it may continue even after 48 hours. In others, it may wear off in 20 hours. Roughly the time taken for developing complete *rigor mortis* is equal to the time for which the *rigor mortis* stays. The same time is taken by the body to wear off the *rigor mortis* as taken for development.

23.5.5 Decomposition or Putrefaction

Decomposition of the body passes through various stages which may indicate roughly the time of death. A number of factors such as temperature (ideal temperature 20 – 40°C), humidity, the health of the victim, the surrounding conditions affect. Likewise, the mode of death is also important. Arsenic, antimony, mercury chloride poisonings delay decomposition of the body. Certain diseases hasten the process.

Internal bacteria are mainly responsible to start the decomposition but external bacteria may invade the body and hasten the process.

Climatic conditions in India vary so much, not only at different places but even at the same place in different seasons, that it is difficult to generalise the decomposition stages. However, the following may act as a rough guide:

1. **Abdomen swelling:** starts in about 24 hours and acquire greenish tinge which spreads to the whole body in about 48 hours. The body also starts emitting a foul smell.
2. **Bloating:** After 2-3 days, blisters containing reddish fluid appear. Simultaneously body cavities are filled with gas. The pressure becomes excessive. Fluid comes out from the body orifices (openings: nose, mouth, rectum, vagina and wounds). Sometimes stomach bursts, but this is rare.
3. **Disintegration:** of body fats and proteins also start. In about 1-2 weeks, skin, hair, and nails are loosened. Brain, liver, kidneys tissues soften and disintegrate and liquefy and flow outside the body. In 4-8 days maggots in the corpse develop into pupae and in 6-12 days they change into flies.

Fig. 23.3

Maggot infested body was found in a secluded hut. only maggots could give idea about the period of death

4. **Adipocere formation:** it takes place in bodies which receive plenty of moisture (bodies under water or in a swamp). The formation is due to the hydrolysis of the body fats to fatty acids which preserve the body tissues. Adipocere formation ordinarily takes 3 to 6 months but under hot and humid conditions it may take even less than a month. Adipocere may be partial or complete. Often it is partial.
5. **Mummification:** it takes place in dry and hot climates. The body is dehydrated by evaporation of the moisture by dry hot air. Complete dehydration (and hence mummification) may take about three months to one year. Bodies suffering from a loss of body fluid prior to death are more prone to dehydration and may take less time for mummification.
6. **Bones change slowly**: they lose organic matter first. They become brittle in consequence. Further, changes involve the complete destruction of soft bones and rarefaction of tough bones. Skull and teeth are destroyed last.

23.5.6 Miscellaneous Factors

Some factors, other than body changes, also help to ascertain the time of death:

- ***Watch and Clocks***

  If the victim was wearing a watch and if it stopped functioning due to damage in the scuffle, it can indicate the correct time of the scuffle and, therefore, possible time of death.

- ***Bladder Contents***

  If a person has been killed in sleep, the bladder contents may give some idea about the time of death. The empty bladder may indicate death soon after sleep whereas a full bladder may indicate death in the early hours. Urine continues to get accumulated in the bladder during sleep.

- ***Stomach Contents***

  Undigested or semi-digested food can fix the time of death if the time and contents of the last meal are known. However, caution has to be exercised. Sometimes the digestion stops due to shock, injury or disease.

- ***Clothes***

  The state of clothes on the person of the victim may indicate the time of death. Cotton clothes are destroyed in about 2 years, woollen clothes in about 4 years and silk clothes in about six years. However, climatic factors and extent of use change the time table.

  Ants and other insects can change the time table completely.

- ***Vegetation***

  If the body has been lying in secluded jungles and vegetation has grown through the skeleton, the death is roughly as old as the age of the vegetation at the site.

- ***Rusting***

  Iron and steel articles, such as keys, rings, nails rust. If such articles are found on the skeletal remains of the deceased, the extent of rusting may give a rough idea about the time of death.

23.6 CAUSE OF DEATH

A person may die of poisoning, shooting or in road accidents. The modes of deaths have already been discussed. Additional causes of death include:

23.6.1 Mechanical Violence

Mechanical violence causes internal and external wounds causing dissolution or discontinuation of body tissues. The 'wounds' embraces a wide variety of injuries.

A wound may involve skin, flesh or bones, individually or conjointly. A wound may be simple, grievous or fatal.

Wounds are classified as:

- Abrasions, grazes, or lacerations
- Bruises or contusions.
- Punctured wounds, and
- Incised wounds.

23.6.1.1 Abrasions

Abrasions are caused by the sliding motion of an object or of the body due to scratching or rubbing of the skin against the rough surfaces such as floors, walls, stones, trees, wooden pieces, rope, string or any other hard and rough surface. The shape and size of the abrasion

vary tremendously. It roughly takes the shape and size of the abrading surface on an extended scale due to sliding contact. In abrasions, ordinarily, only the epithelial layer is involved. The injury heals in about two weeks' time without leaving a scar. If however, deeper tissues have been injured due to deeper scoring a permanent scar may be left.

Abrasions are also known as lacerations or grazes.

23.6.1.2 Bruises

Bruises are also known as contusions.

Bruises are caused by an impact of a blunt weapon like a lathi, club, stone, hammer, shoe, fist, foot or a knee on a body. The impact crushes subcutaneous tissues, rupturing small blood vessels and tearing flesh. Often painful swelling appears at the site.

Bruises are, ordinarily, simple injuries. They prove sometimes fatal when some bones or internal organ is crushed. An injury to head, spinal cord or to a vital organ like heart or testis may cause death.

The shape and size of a bruise correspond to the shape and size of the weapon of offence if the bruise is examined immediately after the impact. Later, the bruise spreads over. It is often not possible to identify the nature of the weapon from the examination of the bruise alone.

Bruises may be accidental, homicidal or self-inflicted. It is often difficult to differentiate between them.

Fig. 23.4

Stab wound in the heart region proved fatal

23.6.1.3 Punctured Wounds

Punctured wounds are caused by pointed and sharp edged weapons like knives, spears, swords, spikes, sickles, and axes. Nails, glass fragments, stones, and firearm projectiles may also cause such wounds.

Punctured wounds have greater depth than length. Outer dimensions of the wounds are ordinarily smaller than the instrument causing the wound.

Fatal punctured wounds, other than firearm injuries, are often rare. They are often homicidal in nature.

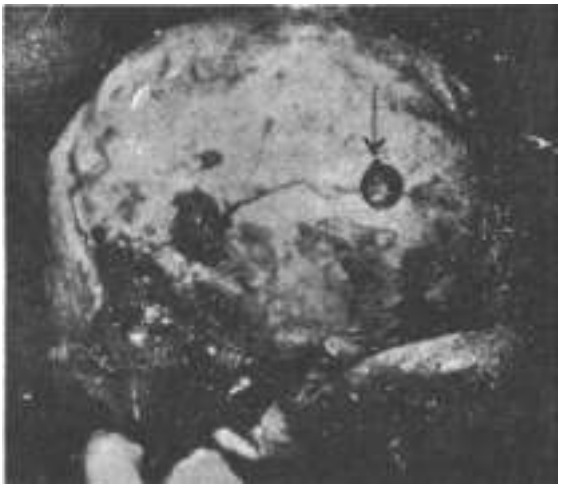

Fig. 23.5

The shape of the injury can some time be misleading. The injury indicated by arrow-head looks like a bullet injury. it was in fact a road accident injury

23.6.1.4 Incised Wounds

Incised wounds are caused by sharp-edged weapons and have clean cut edges. They have a greater length than depth.

Some wounds prove fatal because of:

- Haemorrhage.
- Effusion.
- Shock.
- Complications

Haemorrhage (excessive bleeding) may drain off most of the blood and leave insufficient blood in the body to provide oxygen to various organs especially the brain.

The minimum quantity of blood which must be lost to cause death varies according to the health and age of the victim. The blood continues to flow for sometimes even after death if the wound is large in a prone position. The quantity of blood in a pool is not, therefore, true index of the fatal loss, it may indicate the time of injury in other cases.

The rate of loss of blood varies with the passage of time. It becomes less and less due to clotting and fall in blood pressure.

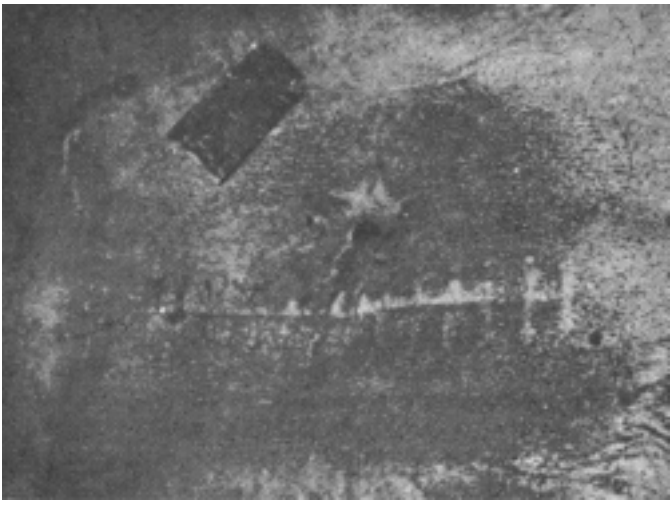

Fig. 23.6

A stab wound was treated in a hospital for a few weeks. Ultimately, the victim died. Does survival for a length of time infer diminished responsibility on the culprit?

23.6.1.5 Miscellaneous

- ***Effusion:*** It is soaking of internal body tissues with blood. If blood effuses into vital body organs such as brain, throat, lungs or heart, it stops their functioning and death ensues.

  Sometimes the wounds causing effusion are not visible, yet they prove fatal (for example head and chest injuries).
- ***Shock:*** It is the fall of blood pressure due to fright or unbearable sight. It may cause death. There may or may not be any mechanical injuries.
- ***Complication:*** Injuries, sometimes, in themselves, are not sufficient to cause death. But they bring in complications in the body functions and cause death. A non-fatal injury may incapacitate a person from moving about. Heat, cold, exposure, hunger or thirst may then kill the victim. The victim may be already suffering from some ailment which is accelerated by the injuries and bring about death. Negligence in the treatment of the injuries has caused many deaths.

  The culprit claims diminished responsibility in such cases, the medico-legal expert should appraise the claim, whenever possible.

23.6.1.6 Dimensions of Wounds

The apparent size of a wound may be smaller than the size of the weapon/projectile causing it. This is due to the elasticity of the skin. The thrust/penetration of the weapon/projectile into the body, stretch the skin When the weapon/bullet leave the site, the skin acquires normal position and assumes smaller dimensions of the wound. This is noticeable, particularly in punctured wounds.

If the weapon is rocked inside, the size of the wound may be larger.

Fig. 23.7

A sword attack or the head cut through the skull, injuring brain resulting in immediate death. the cleavage is seen clearly in the radiograph.

In gaping wound, the width of the wound is larger than the thickness of the weapon. Theelasticity of the skin is responsible for the 'gaping effect'. It is observed in incised wounds.

The dimensions and nature of the edges of a wound may give some idea about the nature of the weapon.

23.6.1.7 Age of Wound

It is not possible to determine the exact age of a wound but a rough idea may be formed from the following factors:

- There is a gradual change in colour of bruised skin. The skin first becomes red and then blue. The colour then starts fading. The time of disappearance depends upon the force of impact, the position of the bruise on the body and the age and health of the person. In some cases, blood clots, do not get dissolved and give permanent blue-black colour unless the same are mechanically removed.
- Inflammation and pus formation may give some idea about the age of the wound.
- Healing scars indicate the age of a wound.
- Formation of callus in bone fractures is a useful indication of the age of the injury. The formation is soft to start with. It hardens with the passage of time.

23.6.1.8 Ante or Post-mortem Wounds

Ante-mortem and post-mortem wounds are distinguished from the following features of the injuries:

- Wounds inflicted on living tissues inflame and heal. Dead tissues putrefy. The difference is noticeable.

- The skin loses its elasticity after death. Therefore, the changes associated with the elasticity of the skin; do not take place when the wound is inflicted on a dead body. However, wounds inflicted immediately after death, may look like ante-mortem wounds.
- Post-mortem wounds do not bleed unless some important vein is cut or the wound is inflicted in a place where blood had accumulated by gravity and flows out from the wound due to gravity. Such bleeding is distinguished from the usual bleeding by the absence of spurting and formation of fibrin (clotting). Spurting and clotting of blood take places only in ante-mortem injuries.
- Blood coagulates in about 12 hours after death. If a wound is inflicted after this interval there will be a very little bleeding.
- The edges of the wounds are deeply and firmly soaked in ante-mortem injuries.
- Bruises cannot be caused on a dead body after a few hours of death. However, sometimes, bruises appear after death for injuries inflicted during life time.

23.6.1.9 Fatal Wounds

It is of great forensic importance to establish whether a particular wound is by itself or principally responsible for the death of the victim. This is established through a detailed and thorough autopsy and study of the medical history of the victim. Certain diseases like weak heart, tuberculosis, asthma, and haemophilia accelerate deaths. Victims suffering from these diseases succumb to violence more easily than normal healthy persons.

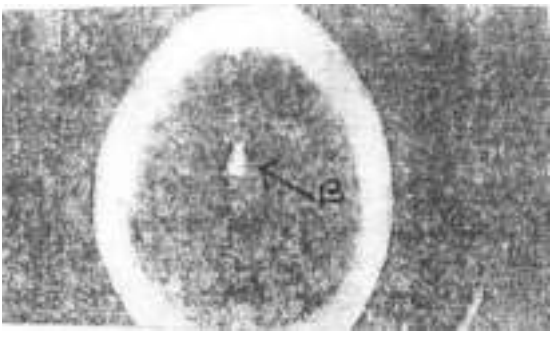

Fig. 23.8

Alive and kicking, even with a bullet (B) in the brain for the last seventeen years. impossible medically?

23.6.1.10 Incapacitation

It is frequently asked whether a victim after receiving a certain injury or injuries could perform the given acts. The medico-legal history is replete with fantastic tales of activities carried out by the injured victims who later collapsed and died.

It appears the will power of the individuals, which vary tremendously, mainly accounts for the unbelievable acts sometimes performed by the injured victims. Ordinarily, any serious injury to a vital organ should incapacitate a person immediately.

23.6.2 Asphyxia

Asphyxia, commonly referred to, is by mechanical means. But it is a many splendoured Phenomenon and includes suffocation, choking, strangling, hanging, drowning and crushing of the heart and lungs.

Asphyxia means the non-supply of oxygen to the body. It may be achieved by chemical or mechanical means.

If the air inhaled contains very little oxygen, as in rarefied atmosphere at high altitudes, or in the air mixed with gases like carbon dioxide and nitrogen in large amounts, asphyxia results. Carbon monoxide or hydrogen cyanide combines with and inactivates haemoglobin, the oxygen carrier in the blood, and causes asphyxia. Certain drugs like opium, inactivate the heart and prevent the supply of oxygen to body parts by restricting the blood circulation, with fatal results In all these cases it is asphyxia.

23.6.2.1 Identification of Asphyxia

Asphyxial deaths are identified from the following observations:

1. Skin becomes pale. Minute droplets of blood may ooze out on the facial skin.
2. Eyes become bloodshot. Pupils become dilated. The eyes remain partially open. If a section of the eye flesh is examined, it shows minute droplets of blood.
3. The mouth remains partially open. Tongue may protrude. Froth is found in mouth, nostril, throat and windpipe.
4. Blood is deficient in oxygen.
5. Marks of violence are found on the body. The nature, number and the position of the marks depend upon the mode of asphyxiation. A person dies in about five minutes from asphyxia.

23.6.2.2 Suffocation

If the inlets of air supply, mouth and nose, are blocked from outside, suffocation (asphyxia) takes place. This is achieved manually by placing hands over the inlets or closing them with a piece of rag or cloth. If the head is buried in a heap of floor, sand, earth, mud, grains, coal dust, snow, water, cotton and wool, asphyxiation takes place.

Suffocation is generally accidental or homicidal, though it can be suicidal.

Accidental suffocation may kill children, drunkards or person suffering from epilepsy. They may bury their heads in pillows, mud, snow or a heap of flour or dust and die.

Homicidal suffocation may carry bruises around the nose and lips as the victim struggles for release.

Being buried alive, accidentally or otherwise, is a form of suffocation. It is ascertained by the presence of foreign matter inside.

23.6.3 Choking

Choking is another variation of suffocation/asphyxia, where the inlet passage of air supply is blocked internally.

Choking may be accidental or homicidal.

Accidental choking may occur when something like a marble or a lump of food is swallowed and gets stuck in the air passage.

A few decades ago, the Chief of Indian Air Force died in Japan due to choking. A piece of meat had stuck in his throat, which choked him to death. (CH)

In homicidal choking, a piece of cloth or other material is pushed through the mouth deep into the throat. The intention of the culprit may not be murder. He only wants to silence the victim but death may follow.

23.6.4 Strangulation and Throttling

Strangulation involves constriction of the neck muscles. The air passage is blocked and the victim dies. Constriction of the neck is caused by an external force. Hands, or a cord, a string, a rope or a piece of cloth may be used.

The neck is marked where the skin is pressed. The skin becomes soft and red. The marks take the shapes of the item used for strangulation.

The death is caused by asphyxia. The neck muscles, arteries, and bones are also damaged. There may be bleeding from the nose and the mouth.

Suicidal strangulation is rather rare and may be accomplished only by lunatics. Accidental strangulation is sometimes possible. Strangulation is generally homicidal. Sometimes it is preceded by drugging.

Throttling is strangulation where only hands and fingers have been used to put pressure on the throat.

23.6.5 Hanging

Fig. 23.9

Hanging death is possible even from insufficient heights. Even if a part of the weight is transferred to the hanging rope or other device, the man loses life

Hanging, like strangulation, involves constriction of the neck. The body is hung by the neck through a cord, string, rope, wire or a piece of cloth. No external force is applied. The weight of the body alone is sufficient to cause death through asphyxia. Damage to neck tissues and arteries and dislocation and fracture of vertebrae may take place, especially in judicial hanging.

> *A corpse was recovered in advanced stage of decomposition. Death due to exposure to elements was suspected. However, fracture of the vertebrae was noticed at the time of post-mortem examination. The case was investigated as a murder. (CH)*

Ligature marks found around the neck on the side opposite to the knot indicate hanging. Detailed examination reveals signs of asphyxia and damage to neck tissues and sometimes to bones.

Hanging is identified from:

1. Dribbling of saliva from the mouth.
2. Elongated neck.
3. The base surface of the groove parchment like.

Hanging was one of the commonest methods for suicide in India. Accidental hanging, though rare, is possible. Homicidal hanging to simulate suicide is frequent. Even dead bodies are 'hanged' sometimes. They may carry the ligature marks but signs of asphyxia are absent.

23.6.6 Drowning or Submersion

Drowning causes asphyxia, though other complications such as dilution and laking of blood, exhaustion, heart failure, hitting against some rock-like hard object may also take place. Persons are known to have died even in shallow waters (or other fluids). Presumably, the victims were too feeble (due to intoxication, drugging, injuries or diseases) to save themselves.

Drowning is recognised by both internal and external changes. Signs of asphyxia, foreign matter in hands, mouth, and inside, abrasions on fingers, toes, knees and forehead and vomitus constitute external signs.

Internally, froth mixed with blood and sometimes with food matter in the windpipe, foreign matter along with water in the stomach, haemolysis of blood and distention of lungs (with frothy bloodstained fluid) and stomach are observed. Identifications of diatoms in body fluids are a reliable test for drowning.

If the body is submerged under water for a long time, the hands and feet acquire 'washerman's skin' and lungs are swollen and congested.

Drowning is often accidental and suicidal; it is rarely homicidal. It is often difficult to decide whether the drowning is homicidal or not. Answers to the following questions help:

1. Is the body tied? If so, it is, ordinarily, homicide. The rope with the knots is preserved. It may virtually tie the culprit with the murder.
2. Are there any homicidal tears, holes, stabs or stains on the clothes of the victim?
3. Are there some injuries on the body? If so, were they present before the body was submerged? Or, are the injuries due to falling in the water and striking against some hard object under water or en route?

4. Are there any fractures or dislocations of bones, bullets or other foreign matter in the body? Could the damage to bones occur inside water due to fall and striking against some hard object?
5. Does the viscera contain poison? The presence of poison indicates either homicide or suicide.
6. Was the deceased of sound mind? Did he have a tendency towards suicide or did he suffer from some disabling disease like epilepsy?
7. Who was interested in his removal?

Sometimes dead bodies are thrown in water for disposal by the murderers. The bodies do not show any signs of asphyxia and there is no foreign matter including water in the bodies.

23.6.7 Miscellaneous

Miscellaneous causes of death include starvation; electrocution; cold and heat. It is often difficult to determine whether the death due to these causes was accidental, suicidal or homicidal in nature.

23.6.7.1 Starvation

Starvation deaths were common previously due to recurring famines. They are very rare now. Starvation deaths are identified from the following:

1. Hollow and shrunken face
2. Absence of fat and muscles
3. Disagreeable odour
4. Loss of body weight
5. Bowls become translucent
6. Excretion track carries a hard crust of stool
7. Shrunken heart, lungs, spleens, pancreas and kidneys
8. Very little blood in the body

23.6.7.2 Electrocution

Deaths due to electrocution are increasing with the increasing use of electricity. They are often accidental and rarely homicidal or suicidal.

A current under 250 volts is considered safe but deaths have occurred even with a current of 50 volts or so. The body built, the clothing and the atmospheric conditions have an important effect.

The electric current affects the heart, brain, and respiratory centres to cause death.

Death due to electrocution is identified from the injuries. There are burns at the point of entry and at the point of exit and reddening en route. If the current has passed through a metal object in its passage, there is burning of the skin at the point. Sometimes there are no visible injuries.

Accidental electrocution takes place due to defective electrical appliances or exposed naked electric points or wires.

Fig. 23.10

Fig. 23.11

Fig. 23.12

Electric burns were found both on chest (Fig. 23.10) and on back (Fig. 23.11). But they did not look so severe. When the body was subjected to post-mortem it was found that even the bones had burnt (Fig. 23.12)

23.6.7.3 Lightning

Deaths by lightning are rare in India. When the static electricity of clouds is discharged with a flash, a high voltage current is generated. It destroys anything in its passage including trees, buildings and individuals.

There are extensive injuries: burning and shredding of flesh. Fractures and dislocations of bones of the body also take place.

Fig. 23.13

Lightning deaths are rare in india, multideaths are rarer still. Yet half a dozen persons were killed when lightning struck the tree under which they were standing

23.6.7.4 Cold

Deaths due to cold are generally accidental. However, infants, children and old people are sometimes exposed to cold deliberately.

The effects of cold vary from simple reddening of exposed parts to their complete elimination due to frostbite when the skin temperature is around -10°C. Physical changes in the heart, lungs, and brain give significant indications. The exposed parts (fingers, toes, ears, nose) are severely affected.

23.6.7.5 Heat

Persons working near hot object, like engines or boilers, perspire heavily. They suffer from heat cramps and may die of exhaustion. Persons working in a hot climate or in closed areas may die similarly.

Heat radiations also cause sun strokes which damage the brain with fatal results.

23.6.7.6 Scalding

Hot fluids, when thrown upon a person, produce scalds (blisters). They sometimes prove fatal mostly due to extreme pain and shock.

23.6.7.7 Burning

Fig. 23.14

Pugilistic pose of a burnt body of a woman. Scalds on face. Scalds on the belly can be easily discerned

Heat, ultraviolet rays and X-ray radiations produce burns. The damage to the body tissues depends upon the source of energy, the length of exposure and the health and the part of the body exposed.

Deaths due to burning are generally accidental. The clothes of the victim may catch fire, a kerosene oil stove may burst or an individual may get surrounded by a big fire. A painful death ensues.

Bride burning has acquired unfortunate proportions in India in recent times. Usually, kitchen accidents are simulated even for murderous burnings. Proper examination of the scene and other evidence helps to discriminate between accidental and homicidal bride burning.

Table 21.1

Ante-mortem/postmortem burning Signs

S No	Evidence	Ante-mortem burns	Post-mortem burns
1	Redness line(s)	Present	Absent
2	Blisters	Blister with serous fluid. Base inflamed	Blisters with watery fluid. Burst easily. Dry base.
3	Vital reaction	Present	Absent
4	Enzymes	Increase in enzyme activity	Does not show
5	CO-Hb	Carboxyhemoglobin > 5% or more. 10 % common. Blood colour change to cherry red	less
6	Soot	Present	Present: passive intake in some

A criminal sometimes sets a house on fire and burns a dead body to simulate accidental burning. However, post-mortem and ante-mortem burns can be distinguished. The latter contain fluid in the scalds and there is inflammation of the skin around the burns. These signs are absent in post-mortem burns.

23.7 MEDICAL NEGLIGENCE DEATHS

The occurrence of deaths and damage due to medical negligence are increasing in India. The aggrieved persons are now filing suits against the doctors for negligence. The number of such cases is increasing.

Medical negligence has been defined as an action, on the part of the doctor, to omit to do something what is normally required to do for the treatment of his patient or to do something, which is harmful to the patient resulting in injury or death to the patient.

Medical negligence includes professional negligence and malpractices, like taking out body organs clandestinely, on their part. It also includes lack of skill, wilful negligence and carelessness on the part of the doctor.

Medical negligence becomes legally actionable when the patient suffers damage, may be immediate or delayed, may be mental or physical, may be financial or it may be affecting the quality of life.

23.7.1 Classification

Medical negligence is classified into two categories:

1. *Criminal Negligence*
2. *Civil Negligence*

Criminal negligence is a gross harmful act, usually resulting in the death of the patient. The police investigate such cases under section 304 A of the Indian Penal Code. The act may also result in serious impairment of the patient.

Other major criminal acts on the part of the doctor involving criminal action are taking out body organs for sale, covertly or otherwise.

> *In a recent case, a gang (at Amritsar and at Jallandhar) would catch hold of persons, intimidate them or promise them with heavy compensation to donate a kidney. The gang member would get them operated to remove one of their kidneys. The subject would not get proper after-operation care and would die or the gang members would kill them to save for themselves the promised compensation. The body would be cremated under a false name. One of the members of the gang, under police interrogation, has admitted of fifteen such cremations. The racket involves not only the gang members but many others also—the doctors, the lawyers and the authorisation committee members, (TOI, 20 November 2002).*

In civil negligence the police are not involved. The affected party sues the doctor for damages. In both cases, he/she has to prove that:

- The doctor was negligent and the damage could not occur but for his negligence.
- He did not perform his duty well.
- The damage to the patient was due to the doctor's failure.
- The patient did not contribute towards the damage.
- The doctor was incompetent.
- The doctor indulged in malpractices.

- He had no regard for human life.
- He showed professional misconduct.

No proof is required if the negligence is self-evidence. Examples:

- Forceps or sponge found inside the victim.
- Two fingers were to be set right; another two also stopped functioning after the operation.

The usual defence taken by a doctor is that the patient or his attendants failed to cooperate, did not follow the suggested treatment or did not attend the treatment schedule as per the advice of the doctor.

Doctor and patient's relationship is that of the implied contract, once the doctor takes up the case, he is supposed to:

- Use necessary care, attention, judgment and skill.
- Use clean and proper appliances. The use of a kitchen knife for removal of piles was condemned by the court in a case.
- Administer proper medicine.

  A doctor gave strychnine in place of quinine. It killed the person. The court held it a case of negligence.
- Give direct intelligible instructions in simple language.
- Continue case until the patient is cured.
- If the disease is beyond his skill he must either consult specialists or refer the case to such specialists or specialist institutions.
- Treat patients while under the influence of liquor or drugs.

23.7.2 Investigator's Role

The investigator's role is a hard task. He has to find evidence, which is often technical in nature. He should proceed systematically. He should procure information about the doctor from his relatives, friends, associate, sub-ordinates, and superiors, other current or previous patients. He should also procure information about death or injury. The following check list help:

23.7.2.1 Death in operation

- Proper record: consent, consultations.
- Proper diagnostic investigation: Biopsy, X-ray, laboratory tests for hypertension, diabetes, drugs in the body?
- Body's adverse reaction to the medicine?
- Haemophilia? ECG?
- Wrong patient, wrong body part, wrong medicine, contaminated drip, incompatible blood transfusion, fat-air embolism?
- Gross negligence: instrument, sponge or swabs inside?
- Cause of death: operational shock, vagal inhibition?
- Criminal wounding for organ theft or otherwise?

23.7.2.2 Post-operational care

Post-operation care is a necessity in most of the cases. Did the concerned doctor take proper care? The check of the following points help:

- Adequate attendance?
- Proper medication/injection at the proper time?
- Plaster too tight, too loose?

23.7.2.3 Anaesthetic deaths

Anaesthetic deaths occur due to negligence, ignorance or lack of proper handling:

- Patient unfit for anaesthesia: under the influence of drug, have sickle cells or heinie infestation.
- Improper dose.
- Basal or wrong gas or ether anaesthesia.
- Prolonged anaesthesia: a person with weak hearts may suffer heart attack.
- Faulty relaxants.

23.7.2.4 Malpractices

Has the doctor indulged in malpractices? The following are common malpractices:

- Theft of body organs?
- Unauthorised termination of pregnancy?
- Foetus sex test
- Experimental transplantation or use of new drugs and medicines

The investigator has to get the help of experienced doctors, both to carry out the post-mortem examination and to understand and prove negligence or other failures on the part of the doctor. He may not succeed alone in many a case.

23.8 IDENTIFICATION OF THE DEAD

The identification of the corpse is necessary to establish the *corpus delicti*. It is done through:

23.8.1 Relatives and Acquaintances

The most reliable identification of a corpse is the one made by relatives and friends. Ordinarily, they do not make mistakes. But when a body has altered greatly, the identity of the deceased should be considered established only if they can indicate specific identification features.

23.8.2 Documents

Certain documents like personal letters, driving licence, passport, permits and receipts may be found on the person of the deceased. They lead to the identity of the corpse.

In some cases, a document may be 'planted' on the deceased to give the corpse an 'identity' which the culprit may desire. The identity, therefore, established from documents should be confirmed from other sources.

A skeleton was recovered from a pit. The flesh and clothes had been completely destroyed by insects. A wrist watch, a steel bangle and a lump of earth suspected to contain a plastic object were recovered. The state of the skeletal remains indicated that the body was lying there for a considerable period. The lump of earth was, therefore, carefully worked to collect its contents. It gave a plastic diary cover containing a crumbled diary, a few coins, bits of currency notes and other papers.

The diary was identified as one issued by a college. The bits of currency notes were found to be at least worth over Rs 600. Some of the bits of paper were suspected to be college fee receipts. Comparison of the writings on one of the bits of paper with duplicate carbon copies in the fee receipt book established original-carbon copy relationship of the documents. The identity of the deceased was, therefore, established.

The recovery of a comparatively large amount of money ruled out robbery or planting of the document to mislead the identity. (CH)

23.8.3 Portrait Parle

The portrait parle of the corpse proves useful. It should be compared with the portrait parle of the suspected deceased or missing persons.

23.8.4 Scars, Fractures, Deformities, Tattoo Marks

The positions, sizes and shapes of scars, tattoo marks, fracture and deformities are helpful.

A fire at the central apartment building in a city recently completely gutted the third floor and heavily damaged the first and second floors of the structure.

An investigation was conducted by the police department and a member of the fire brigade office to ascertain its cause and account for all building occupants. It revealed the fire had originated in apartment 42 and spread throughout the entire third floor. Careless smoking was the probable cause of the blaze.

During their search of apartment 42, badly charred human remains were found in the debris. The remnants of the corpse were taken to the mortuary where a post-mortem examination was conducted. The corpse was so severely charred that identification could not be made by physical appearance, fingerprints or dentures.

All occupants were accounted for except one, a known alcoholic approximately 50 years old, who lived in apartment No. 30 on the third floor and had been seen coming home in an inebriated state about one hour before the fire was reported. It was surmised that the charred remains were his. However, the things that could be established with certainty were: the body was of a male, of the same height and was discovered in apartment 42—not apartment 30. Although this suspected victim was known to wander from apartment to apartment, further identity doubts were formed when another occupant claimed to have seen him leave the building a short time after the arrival of the fire department.

The suspected victim has been known to wear a belt decorated with a World War II medal, the finding of which would assist in identification. In an attempt to locate the medal the pathologist X-rayed the corpse while the police searched the debris. The medal was not found.

The X-rays did, however, reveal that both ankles had previously been fractured. The victim's hospital records revealed similar fractures, comparison of the X-rays of the deceased with those on the hospital file were able to positively identify the body of the suspected victim. (CH)

23.8.5 Professional Marks

A photographer (not a digital photography Worker!), a dyer, a painter, a laboratory worker or a chemist will have stains on their person. A tailor, a draughtsman or a petition writer will have stiffening on his hand. Professional marks reduce the number of possible suspects. Professional dust carried by the deceased is also useful. A colliery worker carries coal particles; a flour mill worker carries flour and so on.

23.8.6 Personal Articles

The personal articles: clothes, shoes, ornaments, a watch, a knife or a pen may carry the name of the manufacturer, the repairer or of the supplier. The clothes may also carry laundry marks.

The shoes carry, in addition, the prints of the feet inside. These prints are compared with similar prints in other pairs of shoes, found at the residence of the suspected victim. They may, thus, help to identify the deceased.

23.8.7 Photographs, Sketches, Casts

Photographs, sketches or casts of modelled features of the deceased should be displayed to the general public. The media of press, police gazette, cinema and television should be used to give wide publicity.

23.8.8 Fingerprints

The deceased may have a fingerprint record. It should be checked. Or, if he has no record, latent prints may be found at his residence. They may identify the corpse.

23.8.9 Dentures

If the deceased has a dental record, it permits the identification of the deceased. The number, nature and positions of the teeth present and lost, peculiarities of arrangement of teeth, crooked, broken, eroded, and additional teeth, presence of bridges and metallic in-lays individualise the denture and hence identify the deceased. Odontology is proving a great help in the identification of the dead persons.

23.9 SKELETAL REMAINS

The evaluation of skeletons and bones is done by forensic anthropologists[2]. They provide a lot of useful information which helps the criminal justice system in many ways:

23.9.1 Human Bones

The structures of certain bones, the jaws, the hands, the feet, and the skull have characteristics, which permit discrimination of human or animal bones. If a number of bones are recovered there is no difficulty to establish the source, but a single old bone may make the task difficult.

Comparatively fresh bones contain organic matter, which gives precipitin reaction with human antisera and thus establishes the human origin of the bones. Through DNA profiling it is now possible to establish eve the identity of the person to whom the bones belong.

2. See chapter "***Forensic Anthropology***."

23.9.2 Number of Victims

It is possible to find out whether the bones recovered in a case belong to one or more than one persons. They are arranged to form a skeleton. If there is no duplication and the bones fit *inter se*, they belong to one individual; otherwise, they come from more than one individual.

Certain bones like vertebrae and mandible are highly characteristic of the human body. They resist decay, fire, and chemicals. There is only one vertebra coccyx in the human body. Their identification and number help to establish the number of victims.

23.9.3 Age of the Victim

The following factors help to determine the age of the victim:

1. **Teeth:** The wear, cement deposit, closing and resorption of teeth, roots and transparency of teeth are helpful.
2. **Roof of Cranium:** The sutures (ossification lines) in the cranium are straight in a young age. They acquire serrated edges and ultimately the lines are covered with calcification. The smoothness and thickness of the surface of cranium are also useful, indicator of age as they change with age.
3. **Ossification of Bones:** The ossification in long bones helps to ascertain the age if the skeleton belongs to a person who had not reached adult age, as it continues from birth to adult age.
4. **Haversian Canal**: The ratio of the internal and external diameters of the Haversian canal of a bone changes with age till the subject has reached adulthood.
5. **Rarefaction of Bones:** Bones rarefy in old age. The extent of rarefaction indicates the age of the victim.
6. **The size, structure, strength** and composition of bone materials of certain bones, especially of fingers and toes, prove helpful to determine the age of the victim.

23.9.4 Sex of the Deceased

It was difficult to determine the sex of the deceased from the bones if only one or a few bones are available. Now, DNA profiling helps

The following bones are helpful to ascertain the sex:

1. Pelvic bone
2. Breast bone
3. Skull
4. Spinal cord

The ratio of the width of shoulders and the hip in general, is more than one in males and less than one in females. Besides, the bones of females are smoother and weaker than those of males.

23.9.5 Height of the Deceased

An idea about the height of the deceased from the skeletal remains is obtained by multiplying the length of a long bone with a suitable multiplication factor. The following factors are useful:

Table 23.2

Long bones Multiplication factors

Humerus	5.2
Radius	6.5
Ulna	6.0
Femur	3.7
Tibia	4.3
Fibula	4.4

The exact multiplication factors vary for males, females and children and for various groups of population. However, the above factors give rough estimate of height in most of the cases.

23.9.6 Identity of the Deceased

The identity of the deceased from skeletal remains is established from the following:

1. **Dentures** of all persons are individual. If the deceased had a dental record, the victim is identified.
2. **Fractures** of bones are individual. The victim may have fractured his bones and the X-rays record may be available. Comparison of the record with the healed fractures may indicate the identity of the deceased.

   A completely charred body was recovered from the debris of a burnt house which was occupied by a single owner. It was suspected that the body belonged to the owner.

   The owner was known to have suicidal tendencies. A few years earlier he had attempted suicide with a firearm. A Radiograph was taken. It indicated several small fragments of projectile lodged inside the body. The fragments were not taken out.

   A Radiograph of the charred remains was taken. It indicated all those fragments in the body at relevant positions. The identity of the deceased was established beyond doubts. (CH)
3. **Deformities** of head, legs, arms and neck are characteristic. They affect the bones. A careful study of the same leads to the identity of the deceased.

   A few years ago, a skeleton was recovered. Its identity could not be established. It was then sent to a medico-legal expert. The expert discovered thickening of the neck bone on one side. He concluded that the deceased had a deformity on the neck. The head hung to one side. The information led to the identity of the deceased. (CH)
4. **Skull** is also used for the identification of the deceased. Identifications from the skull photograph and life size photographs of the suspected victim are made by superimposition techniques. They may indicate the identity or non-identity of the suspect.

   Life size photographs of the head of the deceased and transparency of the skull are superimposed. The positions, of the nose, eyes, ears and chin should correspond. In the case of non-identity, the various positions do not superimpose.

   Three youngsters visited Morni hill, had drinks and drugs. Late in the evening they had an altercation and one of the youngsters was strangulated by the other two. The dead body was thrown in ravines, which are not visited usually by human beings. The skeleton of the body was discovered after a long time. Its identity to that of the boy was established through skull superimposition. (CH)

The following anthropometric measurements of the actual skull, life size photograph and ante-mortem life size photograph of the person are taken and super-imposed *inter se* for a match or non-match:

1. Total face height
2. Face width
3. Upper face heights
4. Lower part face width
5. Nasal aperture; height, width
6. Intra orbital width
7. Orbital height, width.

Seventeen persons were killed in a house collapse in Delhi, a few years ago. It was suspected that vibrations of generator caused the collapse. The bodies of the remnants of 16 persons were identified. The remnants of 17th person remained unidentified. They closed the case after a few months. The intelligence bureau, however, continued to investigate. They found that one of the terrorists was missing from the date of occurrence of this collapse. The intelligence bureau suspected that the terrorist was the 17th dead man in the house collapse.

Skull superimposition technique indicated that the remnants were of the missing terrorist. Presence of RDX in the debris established that the house collapse was due to an explosion, not due to generator vibrations. (CH)

Fig. 23.15

A terrorist who was extensively disfigured in an explosion in Delhi, was identified through skull superimposition technique

In comparison of facial features of ante-mortem life size photograph and morphology of the skull, the following points are measured and compared:

1. Eyebrows
2. Medial margins of the slit
3. Lateral margin of eyes
4. Position of moustache
5. Position of closed mouth
6. Face outline
7. Nasion
8. Position of ear
9. Position of nostrils
10. Height of nose
11. Width of nose
12. Width of mouth
13. Maximum width of the nasal bridge
14. Lip height.

Ruxton case (British) was perhaps the first important case in which the victims were identified from skeletal remains through the superimposition of photographs. The technique proved useful in the differentiation and identification of the two murdered women. The technique has been extensively exploited since its first introduction in that case.

A few years ago, an inmate escaped from a mental hospital. A thorough search of nearby localities proved futile. After about a year, a skeleton was found in a jungle, about 10 miles away from the mental institution. The remains of the clothes indicated that the deceased was an inmate of the mental hospital.

Several patients had run away from the hospital during the past few years. The dental charts were, therefore, checked and compared with the denture of the deceased. The comparison indicated that the deceased was probably the above referred patient.

The exact identity of the deceased was established from a radiograph of the spinal vertebrae taken in the hospital before the patient escaped from the hospital. It tallied with the one taken from the skeleton. (CH)

23.9.7 Burnt Bones

Cremation of dead bodies is the normal way of disposal of the deceased among Hindus. It is also being increasingly used in other countries.

Cremation destroys most of the evidence. However, some parts like teeth may escape destruction. They establish the human origin of the bones. Under favourable circumstances, they may also permit the determination of the identity of the victim.

On burning, the bones lose organic matter. They become brittle and may even be reduced to ash. They leave no substantial evidence. However, the analysis of the ash can indicate that bones have been burnt. The analysis may not differentiate between human and animal bones.

23.10 INFANTICIDE

Infanticide means killing of an infant, a child less than one year old, by acts of omission or commission.

Law does not make any distinction between murder and infanticide in India. The problems of infanticide are peculiar and therefore, need separate treatment. In fact, there is a definite need for separate infanticide laws.

Infanticide was a closely connected crime to abortions for hiding conception and childbirth from sexual intercourses outside wedlock where the child was unwanted. With the liberalisation of abortion laws, this necessity for infanticide has decreased tremendously. Now infanticide is committed only when a doctor refuses abortion for any reason; advance pregnancy age being one of the main causes. Or, a tantric may persuade some ignorant parents or mother to sacrifice an infant.

Property heirlooms are also murdered to grab his property for property. Sometimes an infant is killed for revenge.

23.10.1 Murder

An infant may be killed by acts of commission or omission:

The common acts of omission are:

1. The umbilical cord is not knotted after severing.
2. The infant is not taken out from the mother's discharges.
3. The infant is not protected from the natural elements (heat, cold, rain, wind).
4. The infant is not fed.
5. The child is abandoned at some secluded place.

The infant is killed willfully in the following ways:

1. The infant is suffocated by closing the nose and mouth.
2. The infant is strangulated.
3. The infant is battered, often simulating fall injuries.
4. The neck is twisted.
5. Heart, lungs, liver or head is punctured by needling.
6. The infant is poisoned. Usually, opium is administered.
7. the infant is drowned or buries alive.

23.10.2 Accidental Death

Sometimes the infant dies accidentally:

1. When a mother dies, usually the child in the womb also dies. Only in rare cases, he can be saved.
2. Prolonged labour may compress the infant and kill him.
3. Precipitated (sudden) labour may kill the infant due to fall or drowning in the commode.
4. The umbilical cord may get entangled and strangulate the infant.
5. Some times the infants head is covered with a membrane. It may suffocate the child.

23.10.3 Congenital Defects

In addition to the above, an infant may not survive due to immature birth of the infant, disease, haemorrhage or due to *Rh* incompatibility.

It is unnecessary to go into their details.

23.10.4 Investigator's Role

Investigation of infanticide cases is a delicate task. He must perform the same with tact. The investigator gets different types of evidence:

1. Physical evidence
2. Medical evidence
3. Oral evidence

23.10.4.1 Physical Evidence

The investigator must locate and collect the following:

1. *Corpus delicti, i.e.*, the infant's body or its remnants
2. Evidence relating to the recent delivery
3. Clothes of the mother
4. Clothes used at the time of delivery
5. The instrument used in killing the infant, if any.

23.10.4.2 Medical Evidence

The medical evidence is the most important evidence in cases of infanticide. As the charge of infanticide is a very serious charge, the doctor must confirm that:

1. The infant was alive at the time of birth. The infant was not stillborn.
2. The birth took place recently.
3. The infant was viable and did not suffer from diseases or congenital defects.
5. The infant did not die of natural causes.
6. The death of the infant was homicidal.
7. The injuries on the person of the infant are not birth injuries and could not be caused due to the accident(s) alleged by the mother.
8. Age of the infant.

In addition, medical examination of the suspect mother should reveal that:

1. The mother delivered a child.
2. The delivery was recent (time interval?).
3. The delivery was normal.
4. The mother was normal and she did not suffer from defects, which could cause the death of the infant.

In cases where a mother denies the motherhood of a dead infant, the relationship can be established through DNA.

23.10.4.3 Oral Evidence

The investigator records the statements of the following:

1. The mother and the involved relatives
2. The doctors or persons who helped the mother at the time of delivery and later provided medical support
3. The possible witnesses, involved in the infanticide; or, in the disposal of the body.
4. Chance witnesses who witnessed delivery, infanticide process, disposal of the body and other events. Often neighbours give valuable clues.

23.11 ABORTION

Abortion is the expulsion of products of conception: the fertilised ovum or developing foetus of any womb age prematurely. Sometimes the term abortion is limited to the womb age of conception of three months or more. The terms "miscarriage" and "premature births" are used to indicate un-induced expulsions of foetus which takes place during the third to the sixth month of pregnancy and sixth to ninth months of pregnancy respectively. For our purpose, no such distinction is made.

Abortion may be:

1. Accidental
2. Spontaneous
3. Induced

Accidental abortions are due to some accident the subject may suffer. Fall, extreme grief or emotional disturbance may lead to abortion.

The spontaneous abortions are those which are caused by mal-functioning of the body itself.

The induced abortions are caused through human effort. The latter are classified as:

a. Medical
b. Criminal

Medical abortions are necessitated by medical considerations for the safety and well-being of the mother. Criminal abortions are carried out to terminate unwanted pregnancies. Unwanted pregnancies are not rare among unmarried girls, widows, victims of rape, professional prostitutes and in some cases among married couples whose family size has become too large to permit more additions. Formerly, unwanted pregnancies were terminated illegally.

The law in India has been modified now. Practically any female can get the unwanted pregnancy terminated confidentially in any government approved hospital. Thus, criminal abortions which were a serious problem of substantial proportions prior to these laws have contracted considerably. Now, abortions attract police actions only when the act is performed by a quack under improper conditions. The female may die in the process.

Under Medical Termination of Pregnancy Act, 1971, a medical practitioner can terminate the pregnancy if in his opinion, formed in good faith:

1. *The continuance of the pregnancy would involve a risk to the life of the pregnant woman or of grave injury to her physical or mental health.* ***[section 3(2)(i).]***
2. *There is a substantial risk that if the child were born, it would suffer from such physical or mental abnormalities as to be seriously handicapped.* ***[section 3(2)(ii).]***

Explanation I.—

Where any pregnancy is alleged by the pregnant woman to have been caused by rape, the anguish caused by such pregnancy shall be presumed to constitute a grave injury to the mental health of the pregnant woman.

Explanation II.—

Where any pregnancy occurs as a result of the failure of any device or method used by the married woman or her husband for the purpose of limiting the number of children, the anguish caused by such unwanted pregnancy may be presumed to constitute a grave injury to the mental health of the pregnant woman.

23.11.1 Methods of Abortion

In government approved hospitals abortions are carried out under proper medical care and under hygienic conditions. Usually, curettage and suction are employed after the subject has been properly prepared. Very few deaths occur in the process. For example, in England and Wales in 1972, 157,000 legal abortions were done, only 10 deaths occurred.

Quacks employ a variety of methods, which often prove torturous and sometimes fatal to the subject. The common methods are:

- Violence
- Drugs
- Womb interference

23.11.1.1 Violence

Vigorous massage, exercise, beating, falling, jumping are sometimes employed. They are mostly ineffective. However, at times beating and fall, intended to cause abortions, have actually caused deaths.

23.11.1.2 Drugs

A variety of drugs is employed to secure abortions.

1. They may be purgatives (e.g., castor oil). Purgatives upset the stomach. It is believed they may also upset the womb. Usually, they do not.
2. They may be drugs which promote menstrual flow, (e.g., essential oils, ergot) they are poisonous and sometimes cause deaths. Use of hormones for the purpose may prove safer through absolute efficacy is yet to be proved.
3. There are drugs, which cause contraction of the uterus. For example, quinine and ergot have been used for the purpose but with doubtful results.

23.11.1.3 Womb Interference

Womb interference is an infallible method. It is the ultimate resort of the criminal abortionist. There are numerous methods including the following:

1. Injection of fluids
2. Instrumental interference
3. Electrical interference

Fluids injected in the uterus are hot water, soap solution, corrosive lysol solutions. They cause irritation and may result in abortion. Similar is the action of certain pastes like arsenious oxide, red lead, asafoetida (*Hing*) or even of *madar* juice.

Instruments used by quacks vary tremendously. Nails, knitting needles, bamboo sticks, twigs of certain plants, hair pins, glass rods, and catheter have been used. Usually, the intention is to cause rupture of membrane containing the ovum or foetus. Sometimes the instrument is smeared with certain juices or pastes which cause irritation.

Fig. 23.16

Criminal abortion. Autopsy revealed perforated womb – mechanical interference

Electrical interference is a novel way, which leaves no traces practically unless current causes burns. The negative pole is applied to the vaginal cervix and the positive pole is applied to the sacrum or lumbar vertebra. A suitable voltage is applied. Uterus contracts and its contents are expelled.

23.11.2 Cause of Death

The following are the causes of death in an abortion:

23.11.2.1 Shock

The subject gets shocked due to extreme fright or from reflex vagal inhibition and dies within seconds of the processing of the abortion.

23.11.2.2 Air Embolism

Air may enter into the blood stream through the fluid injected into the uterus. The air bubbles block blood flow and cause death.

23.11.2.3 Haemorrhage

Injuries to uterus or vagina cause excessive bleeding which may result in death.

23.11.2.4 Toxic Effects of Drugs

Certain drugs especially metallic poisons cause toxicity, which proves fatal in some cases.

23.11.2.5 Complications

Complications may develop — acute infection, septicemia, peritonitis and cause death.

23.11.3 Investigator's Role

Due to liberalisation of abortion laws, the number of illegal abortions has come down considerably. Now only those cases come to the police where the subject is dying or has died because an incompetent person negligently attempted abortion. As in the cases of rape, the evidence is of three types:

- Oral evidence
- Medical evidence
- Physical evidence

23.11.3.1 Oral Evidence

1. The statement of the subject who gives information:
   - The persons who took her to the abortionist.
   - The persons at the place where the abortion was done.
2. The statement of the abortionist.
   - The details of the process
   - The time and date when abortion was done
   - The fetal age
   - The fee charged by the abortionist
3. Statements of the members of the family

In case the abortion has caused death, the relevant information about the death has to be collected from relatives and friends. The following questions may help:

1. When did the victim die?
2. When was the abortion done?
3. Who was the abortionist?
4. How old was the pregnancy?
5. What method, instrument, chemicals were employed for abortion? Only abortionist or the witness present at the scene can answer these questions.

23.11.3.2 Medical Evidence

Ascertain from the attending doctor the following facts:

1. If the woman was really pregnant
2. If she had aborted
3. The approximate fetal age

4. Time elapsed since abortion
5. Method of abortion
6. Injuries caused to the subject including inflammation, bruises, scratches, perforations, if any, their size, age, character, and positions.
7. Any foreign material present in vagina or uterus; fluid, chemicals, plant material, device or its fragments
8. Symptoms of any drugs administered orally, locally or by injections.

In cases of death a team of competent medico-legal experts perform autopsy. They also find:

1. If there is any residual material of conception in the womb
2. If there are any injuries to the womb, vagina or surrounding parts inside
3. Signs and symptoms of poisoning if any
4. Immediate cause of death

23.11.3.3 Physical evidence

Physical evidence plays an important role in establishing abortion. The following materials are collected:

1. All vaginal washes or swabs
2. Correct material for toxicological analysis.
3. Residual drugs with the victim or at the scene of abortion.
4. Clothes of the subject.
5. Expelled material, if available
6. Instruments of abortion including syringe and contents of the syringe
7. Any leftover fluids used for facilitating the abortion.

23.13 CASE LAW

Supreme Court Cases – 21st Century

23.13.1 Injury Source in Post-mortem Report[3]

Author's Summary

The High Court substituted the evidence of the expert and that of the eyewitnesses by their own opinion. The SC found no proper base for the substitution and reversed the High Court's verdict.

Highlight italicised

3. *State of Punjab v Jugraj Singh*, AIR 2002 SC 1083 : 2002 AIR SCW 823 : 2002 Cr LJ 1503 (SC).

Relevant Extracts (Verbatim)

The High Court found that the oral evidence of Hardip Singh (P.W. 2) and Sarabjit Singh (P.W. 3) was not consistent with the medical evidence, which was sufficient to hold that they were not the eyewitnesses. Despite the expert opinion that the injuries found on the person of the deceased were gunshot injuries and the injuries caused by a sharp edged and blunt weapon, the High Court plunged into the exercise of finding out as to whether the aforesaid injuries could be caused by gun shots. Keeping in mind the distance between the accused and the victim, as stated by the eyewitnesses, the court held that there was no blackening, tattooing or collar of abrasion or charring on the injuries found on the person of the deceased, they could not have received such gunshot injuries from the distance as detailed by the eyewitnesses. The court found that as in the post-mortem report Exh. PA, it was not mentioned that the injuries found on the person of the deceased were caused by a firearm, the Doctor was not justified to state in the court that the injuries found on the person of the deceased were gunshot injuries. The High Court did not rely on the statement of the doctor and arrived at its own conclusions. The High Court disbelieved the eyewitnesses on finding a number of injuries on the person of the deceased on account of the fact that the eye-witnesses were held to have stated the firing of only two gun shots.

> *The finding of the High Court in this regard cannot be justified. The High Court in this could not substitute its own opinion for the opinion of the expert who had categorically stated that injuries received by the deceased were the gun shot injuries. The statements of the eye-witnesses have not been properly appreciated. Hardip Singh (P.W. 2) had categorically stated that the respondents-accused armed with Double Barrel Guns and the Gandasa had come on the spot. Jugraj Singh, accused raised lalkara that sons of Jagdip Singh should not go alive. Jugraj Singh fired a shot hitting Gurtej Singh on the head, Narinder fired a shot hitting Dosagar Singh in the head near the left eye. Jugtar Singh fired another shot from his gun at Gurtej Singh and Narinder Singh fired another shot on Sodagar Singh from his gun. Thereafter, shots were fired upon the witnesses and when they were running away the sounds of two more fire-shots were heard.*

Nothing could be split out from their cross-examination which could weaken the testimony of aforesaid two witnesses regarding the firing of a number of shots at the time of occurrence. It is to be kept in mind that the shots were fired from the Double Barrel gun and the cartridges recovered show that the firing would have sprayed the pellets all around. In such a situation, it could not be ruled out that the deceased could have received more than one or two injuries. As the witnesses had run away from the spot to save their lives, they could not state as to what happened to the deceased after they were forced to leave the place of occurrence.

> *The testimony of the witnesses could not be discarded only on the ground that they happened to be the relations of that they happened to be relations of deceased.*

Under the circumstances of the case P.Ws. 2 and 3 were proved to be natural witnesses.

23.13.2 Data Essential[4]

Author's Summary

It is a case where the SC superseded the opinion of a medico-legal expert on the cause of death. It gave benefit of doubt to the accused on the basis of quotes of authorities (books). The evidence of the doctor was based upon the postmortem examination of a putrefied body. The SC felt that the evidence was not sufficient to distinguish it as murder from suicide or accidental death.

4. *Mohd. Zahid v State of Tamil Nadu,* AIR 1999 SC 2416 : 1999 AIR SCW 2556 : 1999 Cr LJ 3699. (SC).

Relevant Extracts (Verbatim)

A careful perusal of these circumstances would show that circumstances 1 to 13 either taken together or independently would not assist the case of the prosecution to prove conclusively that the death of Jabeena is homicidal and is not either suicidal or accidental. As observed by the High Court itself the sheet anchor of the prosecution case is the medical evidence which is noticed as the 14th circumstance by the High Court, if the medical evidence is accepted, as has been done by the courts below, then reasons 1 to 13 would provide materials to establish that it is the appellant and the appellant alone who could have caused the death of Jabeena.

On behalf of the appellant, it is strongly contended by Mr. U.R. Lalit, learned Senior Counsel, that the prosecution has not been able to establish that Jabeena's death was homicidal. It is contended, at any rate, the evidence of P.W. 8 creates a reasonable doubt as to the real cause of death of Jabeena. It was further contended that from the material available at the time of the post-mortem, it would not have been possible for a doctor to establish the real cause of death in view of the high stage of decomposition of the body. On behalf of the State, Mr. R. Mohan, learned Senior Counsel, supported the judgments of the courts below and contended that there was no reason whatsoever why the evidence of P.W. 8 should not be accepted.

Since the entire prosecution case rests on the evidence of P.W. 8, we will examine the said evidence in detail.

During the course of the post-mortem examination, P.W. 8 noticed high decomposition of the body. She noted the following injuries on the dead body:

1. Singeing of scalp hair over the middle of frontal and parietal regions 8 cm x 6 cm.
2. Reddish black discolouration of skin over face, front of chest, left breast, right shoulder, right side of abdomen, front of upper and middle third of left leg, front of left leg, front of left thigh, inner aspect of left thigh and upper, middle and lower part of back.
3. Deep splitting of the skin over lower part of right breast and upper thigh of front of right thigh exposing the underlying fatty tissue.
4. Blackening of skin over front and both sides of neck, the skin on the back of the neck did not show any discolouration. The skin on the front of neck showed a horizontal and uniformly hardened and thickened area. 1½ cm. in width, 0.5 cm in thickness and 0.5 cm in length, situated 5 cms. below the right ear lobe on right side of front of neck, 6 cm. below the left ear lobe on left side of front of neck. On dissection of the tissue of neck, a contusion reddish black in colour 4 cm × 3 cm was seen on right side over the right side of hyoid bone and a contusion 3 cm × 2 cm on left side near the left lobe of thyroid.
5. Dark reddish black contusion 14 cm × 12 cm × 1 cm was on the front of right side of chest.
6. There were no burns on left shoulder below the neck and back of neck, upper part of right breast, middle of chest between the breasts, left side of abdomen, genitals, outer aspect of chest and abdomen on both sides, both upper and lower limbs fully, middle and lower part of right thigh, both ankles and feet, buttocks and back of both lower limbs fully.

On an internal examination of the body, P.W. 8 noticed that the lungs were decomposing. Mucosa reddish black in colour was found in the trachea. Very few black soot particles were seen inside the teeth.

Hyoid bone was intact. Stomach was empty. Mucosa in the stomach did not show any discolouration.

Liver, spleen, and kidney were decomposing. Bladder and Uterus were empty. Brain was found liquefied.

On the basis of the above observations, P.W. 8 recorded her opinion of Jabeena's death as follows:

> Died of asphyxia and cerebral anoxia due to cumulative effects of compression of neck and burns.

In her oral evidence, she opined that injury No. 4 noticed by her could be caused by compression of the neck with minimal pressure and the said injury, according to her, was ante-mortem in nature. She opined that the hyoid bone was not fractured because the pressure on the neck was minimal. She further opined that injury Nos. 1 to 3 and the changes found in the trachea along with the presence of soot particles inside the trachea could have been due to burns and that these burns would have been ante-mortem. She was very specific that neither the injury to the neck nor the burn injuries could have been accidental or suicidal.

Thus, it is seen that as per the evidence of P.W. 8, there are two causes of death, namely, asphyxia and cerebral anoxia which cumulatively caused the death and this was due to compression of neck and burns.

During the cross-examination the defence has suggested to her, that the contusion noticed by her as injury No. 4, was not caused by external pressure but due to swelling that were caused during the process of decomposition of the body. Hence, she could have wrongly concluded that death was partly due to asphyxia. To establish that there was a reasonable possibility of P.W. 8 mistaking the swelling caused by decomposition as contusions, the defence confronted her with certain well-recognised textbooks on the subject. *Firstly*, P.W. 8 was confronted with the statement appearing in the text "*Lyon's Medical Jurisprudence*" wherein, at pp 149 and 150 (1953 Edn.), the following statement was found: "Other effects of pressure of gas are: "Distention of the tissues of the neck resulting in accentuation of the natural groove and frequently giving rise to appearances suggestive of strangulation".

P.W. 8 accepted the fact that "*Lyon's Medical Jurisprudence*" was one of the authoritative books on the subject. But, she still disagreed with the statement extracted from the said book without assigning any reasons. However, she did not support her opinion with any other acceptable material. this opinion of P.W. 8 has to be scrutinised in the following background: *Firstly*, the fact that she had not seen any external injury corresponding to the internal contusion which, according to her, was the basis of her opinion that asphyxia by strangulation was caused. *Secondly*, in view of the specific statement made by her in the course of her evidence that she had not seen any ligature marks. *Thirdly*, that the hyoid bone which ordinarily would be damaged if external pressure is applied, was found to be intact.

During further cross-examination, P.W. 8 recognised Keith Simpson as a world authority on medical jurisprudence. But she did not agree with the said Keith Simpson's opinion that Parikh's book is a comprehensive and outstanding book on reference for court work. This reference to Keith Simpson's opinion in Dr. Parikh's book was put to P.W. 8, to suggest to her that if the hypothesis extends to the head, it may be mistaken as a violence to the neck or smotherings as found at p 159 of Dr. Parikh's textbook (4th Edn. 1995). She disagreed with this statement as found in Parikh's book, solely based on her personal experience and not supported by any other authority. While so disagreeing with Parikh's book, she insisted on stating that the horizontal and uniformly hardened and thickened area mentioned by her as injury No. 4 must be due to ligature, even though according to her post-mortem report and evidence in the court, she had not seen any ligature marks on the body of Jabeena.

The defence has further confronted P.W. 8 with the statement found in the book "the Essentials of Forensic Medicine" by Dr. K.S. Narayana Reddy to establish the fact, that on the decomposition of a body, the gas collects in the subcutaneous tissue and becomes emphysematous. This would then create a false impression of ante-mortem obesity (Stout). P.W. 8 disagreed with this opinion also, without supporting her opinion on the basis of any other authority. From the statements found in various textbooks referred to above, notwithstanding the disagreement of P.W. 8, we will have to conclude that there is a possibility of the existence of swelling occurring in a decomposing body, similar to the one noticed by P.W. 8 which give rise to appearances suggestive of strangulation. There is a reasonable possibility that the contusions noticed by P.W. 8 are those swellings which could have been caused due to decomposition of the body of Jabeena. Therefore, these suggestions of defence made to P.W. 8 cannot be lightly brushed aside.

> *More so, in the background of the fact that P.W. 8 had conducted the post-mortem on Jabeena's body nearly 8 days after it was buried, and admittedly even according to P.W. 8, the body of Jabeena had decomposed considerably at the time of the post-mortem examination. This is coupled with the fact that she had admitted in her evidence that she has no other authoritative text to contradict or support her, as against the statements found in the text books like the "Lyon's Medical Jurisprudence", Parikh's textbook on Medical Jurisprudence. The Essentials of Forensic Medicines by Dr. K.S. Narayana Reddy.*

The second cumulative cause of death as per the opinion of P.W. 8 is cerebral anoxia caused due to burns. It is true that P.W. 8 noticed certain burn marks on the face and chest of Jabeena. It is seen from the textbooks and from the evidence of P.W. 8 that anoxia of the brain is caused due to lack of supply of oxygen to the brain which could be due to burning as found in the body of Jabeena, P.W. 8 in her statement before the court stated thus: "Cerebral anoxia means the stoppage of blood supply to the brain. In the event of cerebral anoxia in the post-mortem examination except the pale appearance of the brain, there will not be any other change in the brain. As the brain had been liquefied in this case, it cannot be stated whether brain becomes pale or not. There was no other sign by which I could say that there was cerebral anoxia. Cerebral anoxia in my opinion or conclusion based on my observation and findings in the post-mortem examination. It is not correct to say that no opinion of cerebral anoxia could be given or arrived at in the case of liquidation of the brain". *A cautious reading of this part of P.W. 8's evidence shows in one part P.W. 8 admits that the one and only method by which a medical examiner can conclude that cause of death was due to cerebral anoxia is by noticing pale appearance of the brain. She also specifically admits that there will not be any other change in the brain in the case of cerebral anoxia and since the brain had become liquefied, it cannot be stated if the brain had become pale or not. She is also specific in her statement that there was no other sign by which she could say that was cerebral anoxia.* Stopping for a while at this stage and examining P.W. 8's evidence, one finds that at the time of the post-mortem examination, Jabeena's brain had liquefied and there was no way by which P.W. 8 could have noticed the paleness in the brain. However, in the latter part of her evidence, she deviates from her earlier opinion and states that it is not correct to say that no opinion of cerebral anoxia could be given or arrived at in the case of liquefaction of the brain. These two statements are diametrically opposed to each other and we find it rather difficult to accept this part of her evidence which is so self-contradictory. In our view, the opinion of P.W. 8 that the cause of death as recorded by her is due to the cumulative effect of asphyxia and cerebral anoxia, is rather difficult to accept.

> *We are aware of the fact that sufficient weightage should be given to the evidence of the doctor who has conducted the post-mortem, as compared to the statements found in the text-books, but giving weightage does not ipso facto mean that each and every statement made by a medical witness should be accepted on its face value even when it is self-contradictory. This is one such case where we find that there is a reasonable doubt in regard to the cause of death of Jabeena and we find it not safe to rely upon the evidence of P.W. 8, solely, for the purpose of coming to the conclusion that Jabeena's death is proved by the prosecution to be homicidal.*

23.13.3 Rigor Mortis[5]

Author's Summary

In this case of murder, defence wanted to exploit the presence/absence of *Rigor Mortis* for time of death. SC, quoting chapter and verse, ruled:

"The exact time of death, therefore, cannot be established scientifically and precisely, only because of presence of rigor mortis or in the absence of it."

Highlight italicised

Relevant Extracts (Verbatim)

We may deal with the question as regards presence of *rigour mortis*.

In *'Modi's Textbook of Medical Jurisprudence and Toxicology'*, 21st Edn, at p 171, it is stated:

> *Rigor mortis* generally occurs, while the body is cooling. It is in no way connected with the nervous system, and it develops even in paralyzed limbs, provided the paralyzed muscle issues have not suffered much in nutrition. It is retarded by perfusion with normal saline.

Owing to thet setting in of rigor mortis all the muscles of the body become stiff, hard, opaque and contracted, but they do not alter the position of body or limb. A joint rendered stiff and rigid after death, if flexed forcibly by mechanical violence, will remain supple and flaccid, but will not return to its original position after the force is withdrawn; whereas a joint contracted during life in cases of hysteria or catalepsy will return to the same condition after the force is taken away.

Rigor mortis first appears in the involuntary muscles, and then in the voluntary. In the heart it appears, as a rule, within an hour after death, and may be mistaken for hypertrophy, and its relaxation or dilatation, atrophy or degeneration. The left chambers are affected more than the right. Post-mortem delivery may occur owing to contraction of the uterine muscular fibres.

In the voluntary muscles rigor mortis follows a definite course. It first occurs in the muscles of the eyelids, next in the muscles of the back of the neck and lower jaw, then in those of the front of the neck, face, chest and upper extremities, and lastly extends downwards to the muscles of the abdomen and lower extremities. Last to be affected are the small muscles of the fingers and toes. It passes off in the same sequence. However, according to H.A. Shapiro this progress of rigor mortis from proximal to distal areas is apparent only, it actually starts in all muscles simultaneously but one can distinguish the early developing and fully established stage, which gives an indication of the time factor.

Time of Onset.—This varies greatly in different cases, but the average period of its onset may be regarded as three to six hours after death in temperate climates, and it may take two to three hours to develop. In India, it usually commences in one to two hours after death."

In Parikh's Textbook of Medical Jurisprudence, Forensic Medicine and Toxicology' 6th Edn, at p 3.14, it is stated:

> *Rigor mortis* (rigor-rigidity; mortis of death) is a condition characterized by stiffening and shortening of the muscles which follow the period of primary relaxation. It is due to chemical changes involving the structural proteins of the muscle fibres and indicates the molecular death of its cells.

5. Appeal (Crl.) 1169-1170 of 2005; *Baso Prasad v State of Bihar*, date of judgment 24 November 2006; Bench: S.B. Sinha & Markandey Katju, JJ.; Judgment: S.B. Sinha.

The contractile element of the muscle consists of protein filaments of two types, *viz.*, myosin and actin, which are arranged and organized interdigitating manner. In the relaxed state, the actin filaments interdigitate with myosin filaments only to a small extent but when the muscle contracts, they interdigitate to a great extent due to the presence of ATP (adenosine triphosphate). The production and utilization of ATP are constantly balanced in life. After death, ATP is resynthesised for a short time depending upon the glycogen available locally, but after this glycogen is used up, ATP cannot be resynthesised. This leads to the fusion of myosin and actin filaments into a dehydrated stiff gel resulting in the condition known as rigor mortis. During rigor mortis, the reaction of muscle changes from slightly alkaline to distinctly acid owing to the local formation of lactis acid. Rigor mortis persists until autolysis of myosin and actin filaments occurs as a part of putrefaction. When autolysis occurs, the muscles soften and secondary relaxation sets in.

Rigor mortis can also be broken by mechanical force. Thus, if a limb, which is stiff due to rigor, is flexed forcibly at a joint, the limb becomes flaccid and will remain so thereafter. This is known as breaking of rigor mortis. Existing rigor mortis is broken down at least partially in the process of removal of the body from the crime scene to mortuary, and this may mislead the doctor in estimation of time since death. It is therefore essential to make a note of its stage of development while visiting the crime scene.

All muscles of the body, voluntary and involuntary, are affected by rigor. It first appears in involuntary and then in voluntary muscles. It is not dependent on the nerve supply as it also develops in the paralysed limbs. It is tested by (1) attempting to lift the eye lids, (2) depressing the jaw, and (3) gently bending the neck and various joints of the body."

At p 3.16 it is stated:

> The medico-legal importance is as follows: (1) It is a sign of death, (2) It helps to estimate the time since death. (3) It may give information about the position of the body at the time of death and if it has been altered after rigor has set in. As for example, if a person dies with the hands and legs supported against a brick wall and the position of the body has been hanged after rigor set in, the hands and legs would remain raised in an unnatural position (without support).
>
> The factors which influence rigor mortis are: (1) age and condition of the body (2) mode of death, and (3) surroundings.
>
> Age and condition of the body: In children and old people, rigor develops earlier than in the adults. The onset of rigor is later and the duration longer in the strong muscular person. The more feeble or poorly developed the muscles, the more rapid is the time of onset, and the shorter the duration.
>
> *The exact time of death, therefore, cannot be established scientifically and precisely, only because of the presence of rigour mortis or in the absence of it.*

In *Mangu Khan v State of Rajasthan*, (2005) 10 SCC 374 : AIR 2005 SC 1912 : 2005 Cr LJ 1748, this Court rejected a similar contention, opining:

> In the first place, neither post-mortem report suggests that the death had taken place exactly 24 hours before the post-mortem was conducted. All that the post-mortem reports say is that the death had occurred within 24 hours prior to post-mortem examination. Undoubtedly, the post-mortem examination was carried out at 11.00 am/12 noon on 11 July 1997. In other words, the post-mortem reports suggest that the death might have occurred any time after 11.00/12.00 noon of 10 July 1997. The contention urged by reference to textbooks on forensic medicine to show the time within which rigor mortis develops all over the body also has no factual basis. It depends on various factors such as constitution of the deceased, season of the year, the temperature in the region and the conditions under which the body has been preserved. The record indicates that the body was taken from the mortuary. We notice that there is no cross-examination, whatsoever, of the doctor so as to elicit any of the material facts on which a possible argument could have been based. If these are the circumstances, then the presence of rigor mortis all over the body by itself cannot warrant the argument of the learned counsel that the death must have occurred during the previous night. Acceptable ocular evidence cannot be dislodged on such hypothetical basis for which no proper grounds were laid.

Yet again in *Thangavelu v State of Tamil Nadu,* (2002) 6 SCC 498 : AIR 2002 SC 2759 : 2002 Cr LJ 3558, this Court observed:

> We have heard learned counsel and carefully looked into the material on record. From the evidence of PW-5, the doctor, we find that there is a possibility that the incident in question might have occurred about 39 hours prior to the post-mortem. Though in the examination-in-chief, PW-5 has stated that the time between the death and post-mortem could be 16 to 24 hours which fits in with the prosecution case, in the cross-examination he has very clearly stated that in this case death would have been caused about 39 hours before the post-mortem which would be sometime after 5.30 pm on 15 December 1990. This the doctor has stated by taking into consideration the time and month of the incident as also the time required for the setting of rigor mortis and passing off of the same. According to the doctor, in the month of December in a place like Erode the rigor mortis may set in after about 2 to 3 hours after the death. He has stated that for the rigor mortis to reach from the leg to head, it would take 12 hours and the same would remain in existence for about another 12 hours. Thereafter, it would gradually diminish in the reverse direction *i.e.* from head to leg taking about another 12 hours and on this basis when he examined the body of the deceased, he found the rigor mortis had reversed almost to the end of the legs. By this process he came to the conclusion that the death in question must have occurred about 39 hours before post-mortem.
>
> *(In the instant case) The incident took place in the winter season. The deceased was aged about 50 years. Rigor mortis, thus, would be well marked. Rigor mortis, as noticed hereinbefore, appears after two to three hours. It is well developed from head to foot in about 12 hours. The age, muscular condition and activity before death, manner of death and atmospheric conditions are relevant factors. We, therefore, do not find any merit in the said contention of Mr. Rai.*

23.13.4 Eye-witness Account v Medico-legal Expert Evidence[6]

Author's Summary

This is a judgment in which the SC has given primacy to eyewitness accounts over medical evidence when the eyewitness accounts are consistent, logical, credible and trustworthy. It has also defined reasonable doubt as *'not an imaginary trivial or a merely possible doubt: but a fair doubt based upon reasons and common sense. It must grow out of the evidence in the case.*

On the above considerations, it reversed the HC acquittal in this murder case.

Highlights italicised

Relevant Extracts (Verbatim)

7. A bare perusal of the judgment of the High Court shows that it has disposed of the appeal in a rather casual manner. Most of the conclusions arrived at by the High Court are *per se* not on sound footing. The appellate court will not abjure its duty to prevent miscarriage of justice by interfering where interference is imperative. Where doubt is based on irrelevant grounds or where the Court allows itself to be deflected by red herrings drawn across the track, or where the evidence accepted by the trial court is rejected by the High Court after a perfunctory consideration or where the baneful approach of the Court has resulted in vital and crucial evidence being ignored or for any such adequate reason, the Court should feel obliged to secure the ends of justice, to appease the judicial conscience, as it were. The High Court has noted that the names of witnesses do not appear in the first information report. That by itself cannot be a ground to doubt their evidence as noted by this Court in *Bhagwan Singh v State of Madhya Pradesh,* JT 2002 (3) SC 387 : 2002 Cr LJ 2024 : 2002 AIR SCW 1532 : AIR 2002 SC 1621; *Chittar Lal v State of Rajasthan*, 2003 AIR SCW 3466 : 2003 Cr LJ 3548 : 2003 AIR SCW 3466 and *State of Madhya Pradesh v Man Singh,* (2003) 6 Supreme 202 : 2003 Cr LJ

6. *State of Madhya Pradesh v Dharkole*, AIR 2005 SC 44 : 2004 AIR SCW 6241 : 2005 Cr LJ 108 (SC).

3548 : AIR 2003 SC 3590. There is no requirement of mentioning the names of all witnesses in the first information report.

> **8.** *Coming to the plea that the medical evidence is at variance with ocular evidence. It has to be noted that it would be erroneous, to accord undue primacy to the hypothetical answers of medical witnesses to exclude the eye-witnesses account which had to be tested independently and not treated as the 'variable' keeping in the medical evidence as the "constant".*
>
> **9.** *It is trite that where the eyewitnesses account is found credible and trustworthy, medical opinion pointing to alternative possibilities is not accepted as conclusive.*
>
> Witnesses, as Bentham said, are the eyes and ears of justice. Hence the importance and primacy of the quality of the trial process. *Eyewitnesses' account would require a careful independent assessment and evaluation for their credibility which should not be adversely prejudged making any other evidence, including medical evidence, as the sole touchstone for the test of such credibility. The evidence must be tested for its inherent consistency and the inherent probability of the story; consistency with the account of other witnesses held to be creditworthy; consistency with the undisputed facts; the 'credit' of the witnesses; their performance in the witnesses-box; their power of observation Then the probative value of such evidence eligible to be put into the scales for a cumulative evaluation.*

10. A person has, no doubt, a profound right not to be convicted of an offence, which is not established by the evidential standard of proof beyond reasonable doubt. Though this standard is a higher standard, there is, however, no absolute standard. What degree of probability amounts to 'proof is an exercise particular to each case? Referring to of probability amounts to 'proof' is an exercise the inter-dependence of evidence and the confirmation of one piece of evidence by another a learned author says: [*See* "The Mathematics of Proof II" Glanville Williams; Criminal Law Review, 1979, by Sweet and Maxwell, p 340 (342)].

> The simple multiplication rule does not apply if the separate pieces of evidence are dependent. Two events are dependent when they tend to occur together and the evidence of such events may also be said to be dependent. In a criminal case, different pieces of evidence directed to establishing that the defendant did the prohibited act with the specified state of mind are generally dependent. A junior may feel doubt whether to credit an alleged confession, and doubt whether to infer guilt from the fact that the defendant fled from justice. But since it is generally guilty rather than innocent people who make confessions and guilty rather than innocent people who run away, the two doubts are not to be multiplied together. The one piece of evidence may confirm the other.

11. Doubts would be called reasonable if they are free from a zest for abstract speculation. Law cannot afford any favourite other than the truth. To constitute reasonable doubt, it must be free from an over emotional response. Doubts must be actual and substantial doubts as to the guilt of the accused persons arising from the evidence, or from the lack of it as opposed to mere vague apprehensions. ***A reasonable doubt is not an imaginary trivial or a merely possible doubt: but a fair doubt based upon reasons and commonsense. It must grow out of the evidence in the case.***

12. The concepts of probability, and the degrees of it, cannot obviously be expressed in terms of units to be mathematically enumerated as to how many of such units constitute proof beyond reasonable doubt. There is an unmistakable subjective element in the evaluation of the degrees of probability and the quantum of proof.

> *Forensic probability must, in the last analysis, rest on a robust common sense and, ultimately, on the trained intuitions of the judge*.

While the protection given by the criminal process to the accused persons is not to be eroded, at the same time, uninformed legitimization of trivialities would make a mockery of administration of criminal justice. This position was illuminatingly stated by Venkatachaliah., J. (as His Lordships then was) in *State of Uttar Pradesh v Krishna Gopal,* (1988) 4 SCC 302 : AIR 1988 SC 2154 : JT 1988 (3) SC 544.

13. On that score also the High Court's conclusion that the medical evidence varied with the ocular evidence suffers from vulnerability.

14. It is not necessary for the prosecution to examine somebody as a witness even though the witness was not likely to support the prosecution version. Non-examination of some persons *per se* does not corrode vitality of prosecution version, particularly when the witnesses examined have withstood incisive cross-examination and pointed to the respondents as the perpetrators of the crime.

15. In the instant case the prosecution has indicated the reasons as to why it did not choose to examine the alleged independent persons. There is nothing unusual in the conduct of the eyewitnesses as was inferred by the High Court. The High Court has put unwarranted stress on certain aspects like the political party accused Dharkoke belonged, or the place from where the witnesses came together. The High Court found that the business of the PW-1 was claimed to be a supply of milk, but no sufficient basis have been indicated as to where he was going to sell milk at the time of alleged offence. These minor points do not affect the credibility of evidence and should not have been magnified.

> *Looking at from the aforesaid perspective the judgment of the High Court is indefensible and therefore set aside. It is true that in case acquittal has been recorded the Appellate Court should not lightly interfere with the same. But where the evidence has not been properly analysed or the Court has acted on surmises or conjectures, it is the duty of the Appellate Court to set right the wrong. The case at hand is one where the High Court ignored the relevant aspects and unnecessarily put emphasis on certain aspects which did not have any foundation. That being so, the appeals are allowed and the judgment of the trial court is restored by reversing the judgment of the High Court. The respondents shall surrender to custody forthwith to serve remainder of sentence.*

23.14 ADDITIONAL CASE LAW

23.14.1 *Corpus Delicti*[7]

The next question which in the context of these discoveries arises is whether in the circumstances of this case Kanhiya can be held guilty for murder of Mst. Dhooli and her son Shyoji? The investigating agency could not discover the *corpus delicti* nor is there any evidence on the record to show that both Mst. Dhooli and her son Shyoji died between 6th and 9 March 1972. The prosecution did not take care to bring on record any fact that the bones and pieces of clothes seized near the river either belonged to or could be that of Mst. Dhooli and her son Shyoji. In the absence of any material on record it is difficult to hold that Mst. Dhooli and Shyoji have died. In the view of the matter the charge under section 302, Indian Penal Code for committing murder of Mst. Dhooli and Shyoji cannot be sustained

23.14.2 Oral v Medical Evidence[8]

The wounds and injuries found on the body of the deceased according to the medical evidence were:

1. Incised circular wound all around the neck separating the head from the body.
2. Incised wound from the lower end of sternum to the upper margin of bladder 10″ x 6″ and abdominal organs such as stomach, intestines, and liver were protruding out of the wound.

---

7. *Kanhiya v State of Rajasthan*, 1976 Cr LJ 1652 : 1976 WLN 160 : 1976 Raj LW 251.
8. *Bhagoji v Hyderabad Govt,* AIR 1954 Hyd 196 : 1954 Cr LJ 1378 : ILR 1954 Hyd 130. **Also see**: *Dhanna v State of Rajasthan*, AIR 1951 Raj 37 : 1951 Cr LJ 201 : 1950 Raj LW 357; *Abdul Salam v State of Jammu and Kashmir*, 1953 Cr LJ 1865 : 10 J&K LR 94; *Thakur v State of Uttar Pradesh*, AIR 1955 All 189 : 1955 Cr LJ 473 (All).

3. Incised circular wound over the lower end of the right arm, separating the right elbow joint which was absent.
4. Incised wound on the right side of the head 3″ × 12″ bone deep which was oblique.
5. Incised wound on the left cheek extending left pinna of the ear downwards to the left jaw 6″ × 1″ bone deep.

The learned Sessions Judge has mentioned in his judgment that the head alleged to be recovered from the well exactly corresponded to the incised circular wound of the neck.

I am told that these wounds were caused and truncation effected with the aid of an axe and three inches long knife. In *Mohinder Singh v State*, AIR 1953 SC 415 (N), it has been held that in a case where the death is due to the injuries or wounds caused by a lethal weapon, it is always the duty of the prosecution to prove by expert evidence that it was likely or at least possible for the injuries to have been caused with the weapon with which they are alleged to have been caused. It is no doubt true that the medical evidence is that such wounds could be caused by axe and knife. But it is unfortunate that no question has been put to the expert as to whether the weapon exhibited in the case as material object could cause the wounds as found on the body of the deceased. With the elimination of Rabhaji by reason of his acquittal one is left with a weapon which has been described by the prosecution as "*Ek lokhandi chaku jyache pate teen inch lamba and tayawar raktache dage ahet*", which has been rendered into English as: one iron knife whose blade is three inches long on which there are stains of blood. I am not prepared to believe that a clean and flawless truncation could be effected as shown at (1) and the chopping off as shown at (3) could be effected with the knife alleged to have been recovered from the appellant.[8]

23.14.3 Stomach Contents v Eyewitness Version[9]

There is another aspect of the medical evidence, which, though, not as important as the two aspects mentioned above, may also be referred to. The case of the prosecution is that Ram Sanehi had gone to his *Kharbuza* field with his son and daughter for eating *Kharbuzas*. There is evidence that they did eat *Kharbuzas* and almost immediately thereafter they started back for home. Within less than 5 minutes, Ram Sanehi met with his death near the culvert. The post-mortem report shows that Ram Saheni's stomach was empty which means that the evidence that he had eaten *Kharbuzas* just a little time before his death is untrue. Bal Kishore tried to wriggle out of this situation by saying that Ram Sanehi had eaten just a small slice of *Kharbuza*. But even then, Dr. Pandiya has stated that if the entire slice of *Kharbuza* was eaten by Ram Sanehi, its remains would be found in the stomach provided there was no vomiting after the gun-shot injuries. Since Ram Sanehi had not vomited, his large intestines could not have been found to be empty if the story of his children was true.[9]

23.14.4 Delayed Death[10]

The only question then is whether the accused is guilty of murder; in other words, whether it was the injury inflicted by him that was the cause of the death, and whether he had the requisite *mens rea*. The second part of the question can readily be answered in the affirmative. The accused goes at dead of night to the house of his wife who has left him, and then after locating her with the aid of his torch light, deliberately stabs her in the middle of the back with such force as to penetrate the spinal cavity and cause damage to the cord. The intention could only have been to kill.

9. *Subhash v State of Uttar Pradesh*, AIR 1976 SC 1924 : (1976) 3 SCC 629 : 1976 Cr LJ 1521.
10. *Davasia Yohannan v State of Kerala*, AIR 1958 Ker 207 : 1958 Cr LJ 1021 : 1958 Ker LT 273.

On the second question, the comparatively long interval of seven months between the injury and the death might, at first sight, induce an element of doubt as to whether their relation as cause and effect is not too remote. For, after all causing of death by injury is but the hastening of an inevitable event, and, when that event is so long delayed, the mind is tempted to ask whether the cause of the death is not really to be found in something other than the injury.

This is doubtless the basis of the rough and ready rule of the English common law (so rough and ready that it has not found acceptance in Scotland) that a death which occurs more than a year from the date when the injury was inflicted must be attributed to causes other than the injury and cannot form the basis of a charge of manslaughter or murder. In the present case however, we are satisfied that there is no room for any doubt that both factually and legally the injury was the cause of death. And, although the English rule has no application, we might observe that the death, in this case, is within the time laid down by that rule.

P.W. 9 has said that the injury had affected the spinal cord, and it is apparent both from the post-mortem findings and from the fact that complete paralysis of both the lower extremities was the immediate result of the injury, that the stab given by the accused had pierced the spine between the 6th and 7th vertebrae and cut the spinal cord. As P.W. 9's evidence stands, it would appear that the several sequelae described by her are so directly connected with each other as cause and effect as to make the death attributable to the injury.

There is no indication of any unexpected intervention, and as observed by Mayne at p 469 of his *Criminal Law of India,* 4th Edn. "any act is said to cause death within the meaning of section 299, when the death results either from the act itself or from some consequences necessarily or naturally flowing from that act, and reasonably contemplated as its result". Where without the intervention of any considerable change of circumstances the death is connected with the act of violence by a chain of causes and effects, the death must be regarded as a proximate and not too remote a consequence of the act of violence.

In discussing death from injury we find the following observations at p 238 of Vol I of *Taylor's Medical Jurisprudence* (11th Edn.) under the heading, "Wounds indirectly fatal":

> *Certain kinds of injuries are not immediately followed by serious consequences; but an injured person may die after a long or shorter period, and his death may be as much a consequence of the injury as if it had taken place on the spot. An aggressor is as responsible as if the deceased had been directly killed by his violence provided the fatal result can be traced to the probable consequences of the injury.*

This we consider to be a correct statement of the law. And with particular reference to the injury in this case we might refer to the statement at p 239 of the same book that wounds of the head and spine are particularly liable to cause death insidiously and that in injuries affecting the spinal cord or column, death is not an immediate consequence, unless the wound is above the origin of the phrenic nerves and that injuries affecting the lower portion of the spinal column do not commonly prove fatal for several months, death ensuing later from septic cystitis, bed-sores and toxaemia. Although for the purposes of this classification, Taylor has called such wounds indirectly fatal, in law it does not matter that death is from a secondary cause so long as that secondary cause is a natural consequence of the injury.

In his *Medical Jurisprudence* (11th Edn, p 260) Modi states as follows:

> *When the dorsal (thoracic) vertebrae are injured, the patient becomes bedridden on account of the paralysis of the lower limbs. He also suffers from paralysis of the bladder and rectum, and is always in danger of getting bed-sores and septic infection of the bladder and kidneys, which generally hasten death. Thus, death may occur after two or three weeks, if the upper dorsal vertebrae have been injured; while life may be prolonged for years with partial paralysis of the limbs, if the lower dorsal or the lumbar vertebrae have been fractured.*

In Price's *Medicine* it is observed (at p 1542 of the 9th Edn.) with reference to injuries of the spinal cord that with lesions at lower levels death is liable to take place within a few weeks or months from bed-sores or infection of the urinary tract. It would thus appear that paralysis of the lower limbs and of the bladder followed by cystitis and bed-sores and, in turn, by death are natural consequences of an injury to the spinal cord at its lower levels. And in this connection, we notice that the post-mortem certificate, Ext. p 10, speaks of three large ulcers on the body. These are obviously bed-sores, and so it would appear that the after-effects, in this case, were just those which, according to the text books cause as a result of an injury to the spinal cord in the thoracic region. Death from cystitis and bed-sores is the direct result of paralysis caused by the injury and it would appear that there are not so many links in the chain of causation as the medical evidence by its reference to syncope, asthenia and trophic changes would suggest.

The murder was a cruel and deliberate murder and the fact that death was not as immediate as was probably intended but was after months of suffering is no extenuation.[10]

23.14.5 Diminished Responsibility[11]

There were, however, only two injuries on the body of the deceased and these injuries were not grievous. The medical evidence was to the effect that these injuries could not have ordinarily produced death. If the injuries can be called only the remote cause of death, and death of the deceased is not proximately connected with the act of violence, the appellants cannot be held responsible for causing death, and cannot be credited with the knowledge that such bodily injuries as the deceased sustained were likely to cause his death. It follows that the appellants cannot be convicted for an offence of culpable homicide not amounting to murder. I am, therefore of opinion that the conviction of the appellants must be altered to one under section 323, Penal Code from that under section 304, Penal Code.[11]

23.14.6 Post-mortem -Necessity[12]

But whether it was the injury caused by the passing of the bullet through the body of Ladha which caused his death, is more than we can find. The bullet for aught we know, may not have touched any vital organ of his. Cases have not been wanting in which death has occurred not so much as a result of the injury caused as by the resultant shock. In the absence of medical evidence, it is not safe to say that the death of Ladha was due to gunshot. In these circumstances, the offence made out against the accused is not under section 302, Ranbir Penal Code. We have given our anxious thought to this aspect of the case. We think that section 326, Ranbir Penal Code is the appropriate section under which the accused should be convicted.[12]

23.14.7 Ante-mortem Injuries[13]

It might have been possible to draw that conclusion in an indirect manner if there were convincing evidence on the record on the second point, namely, that it was an ante-mortem injury which caused the child's death. As already stated, the post-mortem report is totally silent as to whether the doctor adopted any method for arriving at this important conclusion. In his cross-examination he admitted that the following six signs establish an ante-mortem injury: (1) haemorrhage, more or less copious and generally arterial, (2) marks of sprouting of blood from arteries, (3) clotted blood, (4) deep staining of the edges and cellular tissues, which is not removed by washing, (5) the edges gap owing to the reaction of the skin and muscle fibres, and (6)

11. *Kanhaiyalal Sewaram v State of Madhya Bharat*, 1954 Cr LJ 6 : AIR 1953 MB 37 : ILR 1953 MB 193. **Also see**: *Chinnathambi (in re:)*, (1952) 2 Mad LJ 550: AIR 1953 Mad 239: 1953 Cr LJ 449 (Mad).
12. *Isher Dass v State of Jammu and Kashmir*, 1954 Cr LJ 505 : AIR 1954 J&K 19 : 10 J&K LR 1.
13. *Vidyamati v State of Himachal Pradesh*, 1952 Cr LJ 33 : AIR 1951 Pepsu 1 : AIR 1951 HP 82.

inflammation and reparative processes. He admitted that, except for sign No. (3) the remaining five signs were absent in the present case. In other words, there were only 17% chances of the injury in question having been caused ante-mortem, while there were 83% chances of its having been caused post-mortem. The medical evidence being thus so overwhelmingly in support of the injury being a post-mortem one, it "would be most unsafe to draw any conclusion from mere conjectures. One such conjecture would be that the appellant would not cause such an injury to the child if it were dead. The learned counsel for the appellant stated that she had given a plausible explanation for that in her confession. For reason already recorded, the confession cannot be looked into, but the explanation can certainly be considered even though it emanates from the appellant's counsel. The explanation given was that the appellant had been advised by her paramour to cut the child because in that way the decomposition would be accelerated. It is immaterial whether any such suggestion had in fact been made to the appellant, or whether it would have worked, it is, however, not beyond the bounds of possibility that the cut may have been inflicted on the infant on the said supposition. It is also possible that the head may have been severed from the body in order to bury the two separately as a safeguard against detection. It is noteworthy that there is no evidence that the body and the head had been buried at one and the same place. When they were discovered they were found at a few feet one from the other. The mere fact, therefore that the head of the child had been severed from the body with some sharp weapon did not lead necessarily to the conclusion that the severance was caused by the infliction of an ante-mortem injury.[13]

23.14.8 Putrefaction[14]

The accused has appealed from jail. The perusal of the record shows that the legality of conviction under section 304(II) is open to question. The body of the deceased was in a decomposed state, at the time of the post-mortem examination. The medical witness could not give any definite opinion as to the cause of death though he expressed the opinion that most probably death was due to the rupture of the spleen. Rupture, he thought, could be caused by striking with a piece of wood or even by a fall particularly if the spleen is enlarged. So advanced was the stage of decomposition that no external injury could be seen.

The opinion that death was in all probability due to the rupture of the spleen particularly if it was enlarged is more in the nature of a hazardous guess than anything else. The fact, therefore, remains that the cause of death could not be found. In these circumstances, conviction under section 304(II) would not be legal. If injuries caused by the accused are not shown to have caused death, the cause would not be covered by section 304(II). It would be equally difficult to place it under section 325, Penal Code as the nature of the injuries is not proved. The accused admits beating. A conviction under section 323, Penal Code is all that is possible in these circumstances.[14]

23.14.9 Drowning[15]

Though the boy was last seen in the morning of 15-11-54, and died according to the prosecution case, on that day, the F.I.R. (E.T. 3) was lodged at Biopartiguda P.S. in the midnight of 21-11-54 six days after the alleged occurrence. The body was removed by the investigating officer (P.W. 17), after being shown the place by the appellant at about 3 am on 22-11-54. The post-mortem examination was held by the medical officer (P.W. 7) at 1 pm on 22-11-54, that is, a week after the alleged occurrence. He found one incised wound at the lower part of the right ear which had cut the internal carotid artery and its neighbouring muscles. There was another incised wound at the right side of the neck lower to the first injury. The post-mortem

14. *Lianthlira v State of Assam,* 1952 Cr LJ 1272.
15. *Adi Bhumiani v State of Orissa*, 1957 Cr LJ 1152 : AIR 1957 Ori 216 : 23 Cut LT 180.

report (Ext. 2) also discloses a sign of ecchymosis at the upper laryngeal part and the body of the hyoid bone as found to be grooved as an effect of some external violent pressure by some fingers. There were also four small simple injuries, one incised wound on the lower part of the chin, a lacerated wound at the distal part of the left tibia, an incised wound at the right iliac region, and a patch of ecchymosis at the left side of the forehead. According to the medical officer (P.W. 7), death was due to shock, haemorrhage and asphyxia. The post-mortem report also discloses that the body was moderately built but swollen, decomposition set in, the cuticle had peeled off, *rigor mortis* was present, eyes were closed, the tongue was protruded, dried mud was present on hands, legs and hair, and hands and feet were wrinkled and bleached. Brain substance was decomposed. Decomposition commenced in the right and the left lungs. The heart was empty and the stomach was empty. But curiously enough Ext. 2 does not contain the opinion of the medical officer whether the injuries found on the body were ante-mortem or post-mortem. One would naturally expect, as it is the object of the post-mortem examination, that the essential thing to be noted in the post-mortem report is whether the injuries are ante-mortem or post-mortem. After the post-mortem report was received by the police the medical officer was again asked to state whether the injuries were ante-mortem or post-mortem and then it was stated by the medical officer that the injuries except one or two were ante-mortem. P.W. 7 in his evidence stated that all the seven external injuries were ante-mortem in nature. But, in cross-examination, he admitted that he had not mentioned so in his post-mortem report and when the police sent a requisition to him on 26-11-54 he opined that except injury Nos. 4 and 6 others were ante-mortem in nature and that he based his conclusion on the post-mortem report. Injury No. 4 is a lacerated wound at the distal part of the left tibia and injury No. 6 is a patch of ecchymosis at the left side of the forehead. He also stated that *rigour mortis* starts after two hours of the death and continues for over seven hours and sometimes it lasts for 2 or 3 days; and that it again starts and vanishes when the body starts decomposing. He also stated that on the region of injury No. 7, a sign of ecchymosis at the upper laryngeal part, he did not find any finger impression. On this evidence of the medical officer and Ext. 2 (the post-mortem report) as also the inquest report (Ext. 4) the learned Sessions Judge came to the conclusion that the injuries were ante-mortem. The learned counsel for the appellant contends that the learned Sessions Judge had not given due weight to the non-mention of that fact by the medical officer in the post-mortem report which was, in the usual course of things, his first duty to state and also that the injuries present can be post-mortem injuries as the dead body was decomposed. In support of his contention he relies upon a passage in *Modi's Medical Jurisprudence and Toxicology*, 12th Edn., at p 133:

> *Owing to the formation of these gases under the skin blisters containing a reddish coloured fluid form on the various parts of the body. When these burst, the cuticle being softened peels off easily. Bruises and abrasions may become unrecognizable when the cuticle is denuded. Wounds, whether caused before or after death, begin to bleed once more owing to the pressure of gas within the heart and blood vessels, wounds also become so altered in appearance that it may be difficult to form an opinion as to whether they were caused before or after death, unless the presence of the clotted blood can be distinctly made-out.*

At p 137, it is stated:

> *The rate of putrefaction of a body in water is more reliable than that of a body exposed to the air or interned, as the temperature of the water is more uniform, and the body is protected from the air, as long as it remains sub-merged in water... Putrefaction is accelerated when once a body has been removed from water, as the tissues have imbibed much fluid. In such a body decomposition is so rapid, that the changes occurring in twenty-four hours exposure to the air will be more marked than those ordinarily resulting from a fortnight's further submersion.*

No doubt, in the case of death by drowning, asphyxia is a common cause in the majority of cases, as water getting into the lungs gets churned up with air and mucus, and produces a fine froth which blocks the air vesicles. It is also stated by Modi at p 170.

> *Occasionally, death may occur from asphyxia caused by laryngeal spasm set up by a small amount of water entering the larynx. In such a case water does not enter the lungs and the signs of drowning will be absent.*

He also states at the same page that shock is brought about by fright or terror, or it may be caused during a fall, the water striking against the chest and pit of the stomach; and that if water is very cold, it may induce shock through the recurrent laryngeal or trigeminal nerves, which reflexively inhibit the action of the heart and lungs and death may also be caused by syncope which may occur in persons suffering from epilepsy by falling suddenly into cold water. Modi also says at p 175:

> *On the other hand, water may not be present in the stomach, if the person died from syncope or shock, or became unconscious immediately after falling into water, so that he could not struggle and swallow water in the act of drowning. There will also be no water in the stomach, if it is present in the stomach, is forced out by the pressure of the gases of decomposition.*

Taylor in his *Principles and Practice of Medical Jurisprudence*, Vol 1, 10th Edn., at p 554, under the heading 'Was drowning the result of accident, suicide or homicide." says:

> *A person may be suffocated, or may die from epilepsy, apoplexy, or from a sudden attack of any other fatal disease which may or may not be indicated by well marked appearances after death; the body is thrown into or falls into water, and remains there a few days. When taken out, water may be found in the lungs, but there may be none in the stomach; there may be no mucus froth in the windpipe, and the lungs may be more or less congested. In the case of a suffocated body without marks of external violence, it would be impossible to determine whether death has actually taken place within the water or not, since persons may die in water or at the moment of immersion, in circumstances in which the appearances of drowning would be either obscure or entirely wanting.*

There is no reason why an adult should not be standing close to the water and fall in when taken with a fatal attack of the disease.

Thus, from the evidence of the medical officer and the post-mortem report, it cannot be said beyond the possibility of all reasonable doubt that the body of the deceased was thrown into the stream after he was killed. The learned Sessions Judge held that the injuries found on the deceased were ante-mortem. He relied upon the medical evidence as also the recovery of the knife (M.O. III) from the house of the appellant's father at Mundiguda to arrive at this conclusion. M.O. III is the knife used for cutting vegetable and identified by P.Ws. 1 and 2 as theirs. It is quite likely that the accused might have had the knife with her at the time of taking the boy to his grand-father's house. He also relied upon the inquest report (Ext. 4) showing that the persons present there noticed three big stabbing wounds respectively at the lower part of the right ear, at the right side of the neck and the lower part of the chin. According to that report, nine persons who attested were of opinion that death was caused by some sharp instrument and the evidence of P.Ws. 9, 11 and 12 was also relied upon to the effect that the dead body disclosed marks of stabbing wounds. The learned Sessions Judge, in my opinion, erred in relying on the statements of nine persons who attested the inquest report that death was caused by some sharp instrument. He also erred in relying upon the inquest report (Ext. 4) in coming to the conclusion that body disclosed marks of stabbing wounds. The evidence of P.W. 9 no doubt should be remembered that he admitted having searched for the body in Tenda Khunto Munda prior to this day. P.W. 11 is the separated younger brother of Pursottam (P.W. 1) and he did not state in his evidence before the learned Sessions Judge that the dead body which was recovered from underneath the water, bore any stab marks though he categorically admitted in his evidence that he was present when the dead body was recovered. The learned Sessions Judge evidently committed an error of record in relying upon the evidence of P.W. 11 that the dead body bore the injuries at the time of its being recovered. P.W. 12 was not examined by the prosecution but was only tendered for cross-examination. He stated that he was present when the dead body was recovered but did not say anything about the existence of the injuries on the dead body at the time when it was recovered. In relying

upon his evidence also the learned Sessions Judge evidently committed an error of record. Practically, the learned Sessions Judge seems to have relied upon the statements contained in the inquest report to arrive at this conclusion. They are not substantive evidence and ought not to have been relied upon by the learned Sessions Judge. On a consideration of the post-mortem report and the evidence of the medical officer especially in view of the fact that it was not noted in the first instance in the post-mortem report that the injuries found on the body are ante-mortem coupled with the statement of Modi in his book on *Medical Jurisprudence* that after putrefaction sets in it is difficult to say from the injuries whether they are ante-mortem or post-mortem. I am of opinion that it cannot be definitely established in this case that the injuries are ante-mortem.

23.14.10 Identity of the Dead — Skull Super-Imposition[16]

The next question is, was it the corpse of Bai Dhanu? We have already discussed the evidence so far as the identity of the corpse is concerned. The corpse was identified to be of Bai Dhanu from the four red plastic bangles and the hair-pin found on the corpse by P.W. 3 Suman Bhaga. From the length of the hair and the find of the hair-pin it could be reasonably inferred that the corpse was of a female. The evidence of P.W. 2 Dr. Barot shows that the bones of the skeleton were packed and sealed in a wooden box and were handed over to the Investigation Officer for the purpose of obtaining the opinion of the Forensic Expert. The forwarding letter, Exhibit 61 shows that the said sealed box was sent to the Director, Central Forensic Science Laboratory, Calcutta, for examination and report. The report received from the Forensic Laboratory is at Exh. 62. Exhs. 64 to 66 are the correspondence on the subject. Now the report of the Forensic expert shows that the hair on the skeleton were identified to be of a human being probably derived from a female. From the hair it was not possible to ascertain the age of the victim. However, on the examination of the bones it was ascertained that they belonged to a female. So far as the question of age is concerned, according to the opinion of the Expert the deceased was of the age group of 20 to 26 years. If we turn to the statement of the appellant recorded under section 313 of the Code of Criminal Procedure, we find his age to be 22 years. His wife must, therefore, be around 20 years of age. As we have pointed out earlier, the enlarged photograph of Bai Dhanu was also forwarded to the Forensic Expert. By his report dated 19 February 1979, which is part of Exh. 62 on the basis of the ratios derived from the measurements of the distance between various anatomical landmarks on the photograph of the skull with mandible as well as on the photograph of the face of Dhanu, the Expert opined that there was a striking correspondence between the mandible and the photograph of the face of Bai Dhanu. The details of these measurements are also found in the said report. From the above evidence two things become abundantly clear, namely: (i) the skeleton was of a female above 20 years but under 26 years of age and, (ii) the measurements of the skull with the mandible of the skeleton when superimposed on the photograph of the face of Dhanu showed a striking correspondence between the two.

It was, however, vehemently argued by Mr. Padia, the learned advocate for the accused, that these findings would raise a suspicion that the skeleton was of Bai Dhanu but a conviction for murder could not be based on a mere suspicion. Mr. Mehta on the other hand contended that once the court finds that the skeleton was of a female about 20 years of age and under 26 years of age from the opinion of the Forensic Expert, the court should have no hesitation in concluding that the skeleton was of Bai Dhanu in view of the find of four bangles and a hair-pin on the corpse, which according to the evidence of the prosecution witnesses, Bai Dhanu usually wore. Mr. Mehta further submitted that in addition to this evidence the conduct of the appellant must also be borne in mind by the court. The prosecution allegation is that the

16. *State of Assam v Upendra Nath Rajkhowa*, 1975 Cr LJ 354.

relations between Bai Dhanu and the appellant were strained because the appellant was keen to get rid of Dhanu as he wanted to marry Manjula. Bai Dhanu was last seen with the appellant in the hutment on the night of 11 December 1978 when they retired to bed. Next morning she was found missing and the appellant trotted out an explanation that she had eloped with some Bhaija. However, the subsequent conduct of the appellant in getting engaged to Manjula post-haste betrays knowledge on his part that Dhanu was no more in this world. Even though the foul smell was emitting from his Navania he remained totally inactive and did not try to ascertain the reason for the foul smell. That also shows that he was aware that the decomposed body of his unfortunate wife was giving out the foul smell. In addition, the evidence discloses that he pledged the silver ornaments through Chhotu Uka soon after the disappearance of Bai Dhanu. The appellant had not given any report to the police at the point of time that his wife was missing. He also offers no explanation regarding the find of the corpse from his Navania. In fact, he goes to the length of disputing his marriage with Dhanu. From all these facts Mr. Mehta submitted that it was safe to infer that the corpse found from his Navania was of Dhanu and none else. We have already dealt with each and every circumstance on which the prosecution relies. We have come to the conclusion that all the circumstances which were mentioned by Mr. Mehta in the course of his submissions have been established beyond reasonable doubt by the prosecution. The only question which now remains to be considered is whether the corpse found from the Navania of the appellant was of his wife, Dhanu.[16]

23.14.11 Skull Super-imposition[17]

Lastly, on the question of the identity of the dead bodies, we come to the expert's evidence.

P.W. 35 is Dr. J.K. Barua. He was Director of Forensic Science Laboratory, Assam in 1970. He is an M.Sc. in Chemistry, Ph.D. in Bio-Chemistry and has a law degree. He had undertaken 3 year's training course in Bio-Chemistry in the National Orthopaedic Institute of London and obtained Ph.D. there. Before becoming Director he was Bio-Chemist in the Pasteur Institute of Shillong. Forensic Laboratory in Assam was established on 2 April 1969 and it started functioning in July, 1970. He came to Dhubri on 14 August 1970 and examined four skeletons remains at morgue of Dhubri. P.W. 35 deposed that the skeletons appeared to him to be of female at the first impression (the witness deposed from a Register). P.W. 35 then looked into the sternum which were found to be of female origin as manubrium portion of the sternum was more than the half of length the entire sternum. He also observed that the pelvic bone cavity was of ovoid structure and the sacrum of the vertebral column was wider in shape and *coccyx* pendulas. In one body there was a union of manubrium with the rest of the sternum body *i.e.*, the entire sternum had fused into one. He also found four braids of long hairs near each skull of four bodies. From the examination, P.W. 35 came to the conclusion that all the bodies were females.

P.W. 35 with the help of his assistants and hospital sweepers cleaned the skulls and also some long bones from each of the dead bodies and packed them and put them in separate packets marking the packets as A, B, C and D. Thereafter they cleaned the skulls and bones in laboratory and examined the humerus bones for ascertaining the height of each of the dead bodies. From his examination we find that the dead body, the bones of which are in packet 'A' was 153.56 cm., in height, the dead body, the bones of which are in packet 'B' was 157.426 cm., the dead body, the bones of which are in packet 'C' was 150.37 cm. and the dead body, the bones of which are in packet 'D' was 156.75 cm. in height. He then took the photographs of the four skulls and they were marked A, B, C and D as per the packet marks. Negatives of the skulls were developed and enlarged prints of those negatives were made to correspond with the life size of skull.

17. *State of Assam v Upendra Nath Rajkhowa*, 1975 Cr LJ 354.

Material Ext. 14 is the group photo of Mr. Rajkhowa, Mrs. Rajkhowa and the three daughters in the group photo Ext. 14 the photo of Mrs. Rajkhowa was marked (1), that of Miss. Linu was marked (2), that of Miss. Luna was marked (3) and that of Miss Bhantu was marked (4). Then they took photograph of the four faces of photos (1), (2) (3) and (4). From the negatives they made enlargement to as near as life size enlargement. The skull found in packet 'A' was marked as (1), that in Packet 'B' marked as (2) that in packet 'C' marked as (3) and that in packet 'D' marked as (4). After so marking they sent these skulls to the Director, Central Forensic Science Laboratory, Calcutta. The braids of hairs, bottles of soil samples, and the group photo material Ext. 14 were also sent to the same officer. P.W. 35 after preliminary examination agreed with the opinion of the surgeon who held the post-mortem regarding the sex. Regarding the identification of skull, he identified the skull 'A' to be that of (1) in Material Ext. 14, 'B' to be of (2) in Material Ext. 14, 'C' to be of (3) in Material Ext. 14, 'D' to be of (4) in Material Ext. 14. The witness has stated sacrum is the end portion of the vertebral column. Female sacrum is wider than that of male. Sternum became fused with the main body at the age of 35 and above. Since the witness has stated that there was union of manubrium with the rest of the sternum body, that is, the entire sternum had fused into one in one skull it is found that one skull belonged to a person of 35 years or more. The witness also has stated that the age of person referable to skull No. 4 would be above 18 years.

In cross-examination P.W. 35 has stated that this was their first examination of the skeletons in the institute and the magistrate had required him to do the examination and he received the requisition (Ext. 23) at Gauhati. He received the group photo from the magistrate. He had not known Mrs. Rajkhowa and her daughters personally. He had established the identity by comparing the face photos with the photos of the skulls. He had found the data to be correct upto 90%. But he wanted to be 100% sure and so he sent the skulls to the Central Forensic Science Laboratory. The witness has stated that identification could be established by anthropometric measurement, that is, by measuring selected distances between different facial anatomical landmarks and finding out their ratios. For this the photos need not be enlarged to life size. To avoid mistakes the skulls and photos were enlarged as much as possible to life size. In sternum there were five pieces of bones. He had inspected the manubrium and when he found that its length was more than half of body length of sternum, he concluded that it belonged to a female body. The witness also has stated that the male skull differs from female skull in many respects.

At pp 27-28 of Modi's *Medical Jurisprudence and Toxicology*, Seventeenth Edition, we found the following:

> *The sternum in the female is shorter and its upper margin is on a level with the lower part of the body of the third thoracic (dorsal) vertebra, while in the male it is on a level with the lower part of the body of the second. The sternal body is less than twice the length of the manubrium in the female. While, it is more than twice its length in the male. This is due to the fact that the manubrium in the male is somewhat smaller than that in the female. The ribs are thinner and have a greater curvature, and the costal arches are larger.*

The pelvis affords best marked and most reliable characteristics for distinguishing sex in over 90% of subjects. The female pelvis is shallower, wider, smoother and less massive than the male pelvis. The ilia in the female are less sloped, their posterior borders, are more rounded, the anterior superior iliac spines are more widely separated and the great sciatic notches are much wider, forming almost a right angle than in the male. The female sacrum is short and wide, and is sharply curved forward in its lower half, while the male sacrum is long and narrow, has a uniform curvature along its whole length and may have more than five segments."

P.W. 21 Basudev Bhattacharjee is the Assistant Director, Central Forensic Science Laboratory-Cum-Assistant Chemical Examiner he had deposed that he has been Assistant Director since February, 1968 and before that he was a Junior Scientific Officer of Central Forensic Laboratory. He is an M.Sc. in Zoology and Comparative Anatomy. He has acquired

experience under the then Assistant Director for examination of biological materials including photographic super-imposition. On 31-10-70 he received 9 parcels from the Director, Forensic Science Laboratory, Assam, under Memo. No. F.S.L. IV/67/70/984, dated 27-10-70 in connection with the present case. In his deposition he has given the details of the articles received in those 9 parcels. On examining the articles he stated the result of his examination as follows:

> Each of the four samples of hair contained in packets marked 1(b), 2(b), (3)(b) and 4(b) respectively was identified to be human head hair probably derived from adult female.

Neither arsenic nor any metallic poison could be detected in the hair samples sent for examination. The report on photographic super-imposition of skull of each of the four skulls is as under:

(a) There was a correspondence between the anatomical landmarks of the skull marked 'I' (M. Ext. 18) and the photograph of the deceased face marked (1) in the group photograph (M. Ext. 14) when photographically super-imposed. It is, therefore, concluded that skull in question marked 'I' could have been the skull of deceased person shown as (1) in photograph (M. Ext. 14).

(b) There was a correspondence between the anatomical landmarks of the skull marked '2' (M. Ext. 20) and the photograph of the deceased face marked (2) in group photograph when photographically super-imposed. It is, therefore, concluded that the skull in question marked '2' could have been the skull of deceased person shown as (2) in the photograph (M. Ext. 14).

(c) There was a correspondence between the anatomical land marks of the skull marked '3' (M. Ext. 22) and the photograph of the deceased marked (3) in group photograph (M. Ext. 14) when photographically super-imposed. It is, therefore, concluded that the skull in question could have been the skull of deceased person shown in the group photograph as (3).

(d) There was a correspondence between the anatomical landmarks of skull marked '4' and the photograph of deceased face marked (4) in group photograph when photographically super-imposed. It is therefore concluded that the skull in question could have been the skull of a deceased person shown in the photograph as (4).

The report submitted by P.W. 21 to the Director, Forensic Science Laboratory, Assam in Ext. 25.

P.W. 21 has stated that in case of skull No. 1 with photo marked (1) in M. Ext. 14 there was a correspondence of Nasion point, sub-nasion point, prosthion, the canthuses molar prominence. By Nasion is actually meant a point where the two nasal bones meet the frontal bone. By sub-nasion is meant the uppermost point below the nasal aperture where the two maxillae unite at the mid segittal plane is the skull. Prasthian in the lower-most point of maxilla at the mid seggittal plane. Canthuses are epicanthus and indocanthus, which correspond to outer and inner angle of eye. The cheek bones are molar prominences. The above correspondence was found in respect of all other skulls and photos.

Shri R.C. Bannerjee (P.W. 22) the photographic expert took the photos. Shri Bannerjee had measured the anatomical landmarks of the skull and photos in his presence. After getting the measurements, they arrived at certain ratios and Shri Bannerjee arrived at those figures. In the skulls the anatomical landmarks are at a particular distance from each other. If identical differences in the photos are found there is a further help in establishing the identity of the deceased. Mr. Banerjee had sent his report to him (P.W. 21). The ratios indicated a striking correspondence between the skulls and their respective photos thereby leading them to believe that the skulls were of the same person whose respective photographs were examined by them.

Dr. W.M. Crogman in his book *Human Skeleton in Forensic Medicine*, has recommended a skull photograph comparison whenever possible making allowances for a degree of non-comparability in the head positioning in the photographs as relating to far more precisely oriented cranial positions. Important corroborative and possible conclusive evidence may thus be established.

In cross-examination P.W. 21 has stated in their laboratory other examinations are also conducted. Superimposition is one of the methods of identification. There are surer means of identification—in general than superimposition. In this case he had only received the skulls. If other pieces of skeletons would have been sent to them they would have been in a position to give age, sex and height of the person. They had definite instructions to find out identity by superimposition. The term superimposition means the comparison of skull with a photo and superimposition would mean 2 photographs being combined in one—these two photos are of 2 existing things. They are then brought to the same plane and enlarged to the same size for purpose of comparison. He did not get a perfect contour of the skulls as lower jaws were missing in the skulls and some portion of bony fragments were also missing in all the skulls. The original contour was therefore partially missing (absent). The degree of partially missing bone was negligible in the present case as immovable bones were not missing and lower jaw is a movable one only. It could not have been possible to know about the position of lower jaw from the photographs. The absence of lower jaw would alter the contour partially. Superimposition would not be imperfect, even if lower jaw is missing. It is not a fact that superimposition would be erroneous in such a case. The skulls were marked (1) to (4) as in group photos by the sending authorities. Nobody of the sending authority was personally present at time of super-imposition for identification. He had taken part in measurements of the anatomical land marks. He agreed that measurement in skulls were bigger than the measurements in the photos. So the skulls and photos were not brought to the same size. It was however necessary to have done so. In this case the image of the skull was brought to the size of the photo—though this has not been mentioned in his report. Mr. Bannerjee had enlarged the photo of the face from group photo. He stated that it was not a fact that the skull and the face-photo were not adjusted to same plane. That the negative test of superimposition is more empathic than a positive test.

P.W. 22 is Ram Chandra Banerjee. He is Scientific Assistant of Central Forensic Science Laboratory. He knew P.W. 21, Mr. Bhattacharjee. He had helped him in preparing a report. He had seen the skulls received in their laboratory. He took measurement of anatomical land marks of all the skulls. In his deposition he has given the various measurements. P.W. 22 stated that he arrived at the ratio by dividing the length of two anatomical points in a line with another anatomical points in the line. The witness explained the ratio given in his deposition.

Considering the evidence of P.W.s 21 and 22 we are inclined to hold that though the superimposition in the instant case is not perfect we find that the ratios indicated a striking correspondence between the skulls and their respective photographs thereby leading to the conclusion that the skulls were of the same persons whose respective photographs were found in M. Ext. 14.

23.14.12 Skull Superimposed Photographs Admissible[18]

There was some argument before the Sessions Judge and the High Court as regards the admissibility in evidence of the superimposed photograph as a means of identifying the skeleton as that of the deceased and it is this legal objection raised by the appellant that forms the ground of the certificate granted by the learned judges of the High Court. Learned counsel

18. *Ram Lochan Ahir v State of West Bengal*, AIR 1963 SC 1074 : 1964 Mad LJ (Cri) 19 : (1963) 2 Cr LJ 170 (SC).

urged before us that the superimposed photograph was not admissible in evidence and that its reception vitiated the verdict of the jury. We are clearly of the opinion that even if this photograph was not admissible in evidence the verdict of the jury and the conviction of the appellant could not be set aside because there was very cogent other evidence to prove the identity of the skeleton. Since, however the learned judges of the High Court have thought fit to grant a certificate, though they were themselves conscious of the fact that besides the photographs there was plenty of the other evidence to sustain the conviction, we consider it proper to express our opinion on the question.

The process adopted for taking the superimposed photograph is explained by P.W. 18, the assistant chemical examiner of the West Bengal Government was this: He first got a photograph of Pancham Sukla. This was photographed, the negative being taken on a quarter plate and the negative was enlarged. He got the skull and as the skull was broken in some parts the bones were pieced together and an enlarged photograph of the skull as reconstructed was taken. A negative of this was enlarged to the same size as the negative of the photo of the deceased with the angle and positions of the two being identical. The two negatives were then superimposed. For the superimposition the technique employed by him was thus explained:

> The ground glass of the camera was taken out, the negative of the photograph alleged of Pancham Sukla was placed on it, prominent markings of the negative were carefully jotted down on the ground glass, the markings being the following, *viz.*, nasion-nasomental line, malar bone prominences and two outer canthuses and two inner canthuses of the two eye balls and the inner ends of the supra orbital ridges, thereafter the ground glass was fitted in the camera, the skull was so orientated that all the points of the skull came in exact position with the markings made on the ground glass as mentioned when the photograph of the skull was taken; then the two negatives were placed by aligning in such way that all the points as mentioned above corresponded on a sensitive bromide paper under an enlarger. The resultant is the photograph submitted to the court.The photographer who executed this work under the supervision of P.W. 18 was Tapendra Nath Majumdar, who was examined as P.W. 19. This superimposed photograph showed the shape and contour of the bones of the face underneath the face as it looked when the deceased was alive, and the prosecution sought by means of this document to establish the identity of the skull as that of the deceased, or in any event to dispel any positive argument for the defence that the skull was not that of the deceased.

The contention urged before us by learned counsel was that this photograph was not admissible under any section of the Indian Evidence Act. If learned counsel is right here, he could succeed in having this evidence rejected as inadmissible. We are, however, clearly of the opinion that it is admissible in evidence under section 9 of the Evidence Act, the section reads:

> Facts necessary to explain or introduce a fact in issue or relevant fact or which support or rebut an inference suggested by a fact in issue or relevant fact, or which establish the identity of anything or person whose identity is relevant, or fix the time or place at which any fact in issue or relevant fact happened, or which show the relation of parties by whom any such fact was transacted, are relevant insofar as they are necessary for the purpose.

The question at issue in the case is the identity of the skeleton. That identity could be established by its physical or visual examination with reference to any peculiar features in it which would mark it out as belonging to the person whose bones or skeleton it is stated to be. Similarly the size of the bones, their angularity or curvature, the prominences or the recessions would be features which on examination and comparison might serve to establish the "identity of a thing" within the meaning of section 9. What we have in the present case is first a photograph of that skull. That a photograph of the deceased was admissible in evidence to prove his facial features, where these are facts in issue or relevant facts, is also beyond controversy. Now what P.W. 18 with the assistance of P.W. 19 has done is to combine these two. The outlines of the skull which is seen in the superimposed photograph show the nasion prominences, the width of the jaw bones and their shape, the general contours of the cheek bones, the position of the eye cavity and the comparison of these with the contours, of the face of the deceased as seen in

the photograph serve to prove that features found in the skull and features in the bones of the face of the deceased are identical or at least not dissimilar. It appears to us that such evidence would clearly be within section 9 of the Evidence Act.

The learned counsel for the appellant urged that the superimposed photograph was not a photograph of anything in existence and was for that reason not admissible in evidence. This argument proceeds on a fallacy. In the first place, a superimposed photograph is not any trick photograph seeking to make something appear different from what it is in reality. There is no distortion of truth involved in it or attempted by it. A superimposed photograph is really two photographs merged into one or rather one photograph seen beneath the other. Both the photographs are existing things and they are superimposed or brought into the same plane enlarged to the same size for the purpose of comparison. Possibly some illustrations might make this point clear. For instance, if the photo of the deceased when alive were printed on a transparent medium and that were placed above a photograph of the skull— both being of the same size—the visual picture seen of the two together would be approximate to the document objected as inadmissible. In the above, it would be seen both the photographs would be admissible in evidence and no objection could be taken to their being examined together. Again for instance, if instead of a two-dimensional photograph we had first a hollow model of the head of the deceased say of transparent or semi-transparent material, constructed or made from a photograph, that certainly would be admissible in evidence provided there was proof that the model was exactly and accurately made. If the model were dismantled into segments and placed upon the skull with a view to show that the curves and angles, the prominences or depressions, exactly corresponded, there could be no dispute that it would be a perfect method of establishing identity. If this were granted the superimposed photograph which is merely a substitute for the experiment with the model which we have just now described would be equally admissible as evidence to establish the identity of a thing. It was pointed out that this was the first occasion that in India an identity of a skeleton was sought to be established by means of superimposed photographs and that P.W. 18 had done this experiment by reference to what he had read in the books on the subject and that on that ground the evidence could not be accepted. Any deficiency in scientific accuracy might go to the weight of the evidence which in the case on hand was a matter for the jury to consider, but we are now only on a very narrow question as to whether it is excluded from evidence as inadmissible. Our answer is that it was admissible in evidence.

23.14.13 Bladder and Stomach Contents (Time of Death)[19]

Another circumstance which has been magnified by the learned Additional Sessions Judge is the discovery at the time of post-mortem of not less than 2 Ibs. of semi-digested food in the stomach and 12 ounces of urine in the bladder of the deceased Gurdit Singh. It is said that this circumstance demonstrates that the said deceased must have taken his food and must be sleeping when he was murdered, for if he was murdered at 5.30 pm as the witnesses deposed, there would not have been such semi-digested food in the stomach of the deceased or such a large quantity of urine in his bladder. The High Court pointed out that the said circumstances cannot afford a reliable basis for ascertaining the time of death, particularly when there is nothing on the record to show that the deceased had not taken any food a couple of hours before he was attacked. Apart from the fact that the time required to digest food varies depending upon the nature of the food taken, the digestive capacity of the individual concerned and his health at a particular time, it is also not possible to rely upon such evidence unless there is some definite evidence that the deceased had not taken any substantial food within a few hours

19. *Nihal Singh v State of Punjab*, AIR 1965 SC 26 : 1965 (1) SCJ 160 : 1965 (1) Cr LJ 105 (SC). **Also see**: *Ambika Prasad v State (Delhi Adm.)*, AIR 2000 SC 718 : 2000 Cr LJ 810 : 2000 AIR SCW 253 (SC); *Satbir Singh v State of Haryana*, 1995 Cr LJ 739 : 1995 (2) Cri CJ 395 : 1995 (2) Crimes 777.

before his death. Without such definite data, a court cannot come to any conclusion on the general habit of villagers taking lunch at 1 pm and dinner at 7 pm. The capacity to retain urine for a longer time than usual depends upon individual habits. That apart, this aspect of the case was not pursued in the cross-examination of the doctor and no question was put to her on the basis of the said two factors. The High Court was, therefore right in holding that the learned Additional Sessions Judge was wrong in giving undue importance to the said circumstances.

23.14.14 Digestion Time Variable: (No guide to TOD)[20]

The learned counsel for the appellants pointed out that the doctor who performed the post-mortem examination of the corpses, found partially digested rice in the stomach of the two deceased persons, and he urged that from this it would be inferred that the occurrence must have taken place sometime at night after the deceased persons had taken their evening meals together. This argument again raises a question of fact which the High Court has not omitted to consider. It may, however, be stated that a reference in books on medical jurisprudence shows that there are many factors affecting one's digestion, and cases were cited before us in which rice was not fully digested even though considerable time had elapsed since the last meal was taken. There are also no data before us to show when the two deceased persons took their last meal, and what article of food, if any, was taken by them along with rice. The finding of the doctor, therefore, does not necessarily affect the prosecution case as to the time of occurrence.

23.14.15 TOD from Food Digestion[21]

The contention of counsel for the respondents before us, which has received judicial reinforcement by acceptance by the Sessions Judge, is that this first information is a product of many minds manipulating to make it, and the apparently short, honest interval between the occurrence and the report to the Patil is a make-believe, the death having occurred beyond doubt at about 2.00 pm and not at 5.30 pm as the prosecution disingenuously pleads. Reliance is primarily placed for this preclocking of the occurrence on the post-mortem certificate, doctor's evidence and the medical expertise contained in Modi's *Medical Jurisprudence*. Admittedly, 'semi-digested solid food particles, were observed in the deceased's stomach by P.W. 4, the medical officer, and the inference sought to be too neatly drawn there from is that the man must have come by his end (and that the digestive process must also have come to a halt with it) 2 to 3 hours after his last lunch, which, according to P.W. 2, was at 10.00 am. If he did die before 2.00 pm, everything else in the prosecution evidence became suspect, argued the court. The assurance of this assertion, however, turns on the exact accuracy, in terms of the I.S.T., of the testimony of P.W. 5 who swore that himself and the deceased had taken food on the fateful day at about 10.00 am before setting out for Bibi. The sluggish chronometric sense of the country-side community in India is notorious since time is hardly of the essence of their slow life; and even urban folk make mistakes about time when no particular reason to observe and remember the hour of minor event like taking a morning meal existed, 10.30 am could well have been an hour or more one way or the other and too much play on such slippery facts goes against realism so essential in a testimonial appraisal. More importantly, the court must not abandon a scientific attitude to medical science if it is not to be guilty of judicial superstition. To quote Modi's *Medical Jurisprudence* that food would be completely digested in four to five hours or to swear by the doctor to deduce that death must have occurred within 3 hours of the eating and, therefrom, to argue that the presence of undigested food in the dead body spells the sure inference that death must have occurred before 2.00 pm is to misread the science on

20. *Lachhman Singh v State of Punjab,* ILR 1952 Punj 278 : 1952 Cr LJ 863 (SC). **Also see**: *Basappa Bhimappa Doddamani v State of Mysore*, AIR 1961 Mys 21 : 1960 Mad LJ (Cri) 808 : (1961) 1 Cr LJ 120 (Mys); *Laloo v State of Rajasthan*, AIR 1953 Raj 214 : 1953 Cr LJ 1853 : ILR (1952) 2 Raj 602.
21. *Shivaji Sahebrao Bobade v State of Maharashtra*, AIR 1973 SC 2622 : 1973 Cr LJ 1783 : 1973 2 SCC 793.

the subject of digestive processes. Modi's *Medical Jurisprudence* extracts from which have been given by both the courts, makes out that a mixed diet of animal and vegetable foods, normally taken by Europeans, takes 4 to 5 hours for digestion while a vegetable diet, containing mostly farinaceous food usually consumed by Indian does not leave the stomach completely with 6 to 7 after its ingestion. Indeed, the learned author cautiously adds that the stomach contents cannot determine with precision the time of death "inasmuch as the power of digestibility may remain in abeyance for a long time in states of profound shock and coma". He also states "it must also be remembered that the process of digestion in normal healthy persons may continue for a time after death". The learned judges reminded themselves of the imponderables pointed out by Modi which makes the 'digestive' testimony inconclusive and, therefore, insufficient to contradict positive evidence, if any, about the time of death. To impute exactitude to a medical statement oblivious to the variables noticed by experts and changes in dietary habits is to be unfair to the science. We are not prepared to run the judicial risk of staking the whole verdict on nebulous medical observations. Given so according to P.W. 5 deceased took tea some time after 12.30 pm when they started for Bibi. At that time the possibility of his having had something to eat is not ruled out. If so, the medical evidence as to the time of death will not be inconsistent with the post-mortem findings.[21]

23.14.16 Putrefaction[22] (TOD indicator)

The next factor to be considered is decomposition, which according to the doctor had not yet set in. Here, the table regarding the chronological sequence of putrefactive changes in the temperate region on pp 127 and 128 of Modi's book the only change which could have been expected to take place within the period in question is that numbered 1, namely, greenish colouration over the iliac fossae and the eye-balls soft and yielding, the time for which is given as from 1 to 3 days after death. The item 2 in the table is apparently only expected to be seen from 3 to 5 days after death and in the present case even according to the prosecution, the post-mortem examination took place well within three days of the death. Here again, the external conditions would appear to be strongly in favour of late development of putrefaction. Four factors are enumerated by Mr. Modi at p 132, the 4th, namely manner of burial being irrelevant in the present case as the body was left lying in the open. The other three factors are warmth, moisture and air regarding which Mr. Modi has the following to say:

1. *Warmth*

   Putrefaction commences at a temperature about 50°F., and is most favoured between 70°F. and 100°F. and even upto 115°F. The rapidity of the change considerably lessens as the temperature advances above 100°F. It is altogether arrested below 32°F. and above 212°F. A high temperature accompanied by dry air generally retards putrefaction.

2. *Moisture*

   This is very essential for the occurrence of putrefaction, as the micro-organisms, which are the causative agents of decomposition thrive well in both heat and moisture. Hence, the organs which contain water decompose more rapidly than dry ones.

3. *Air*

   The presence of air promotes and its absence retards putrefaction. Closely fitting clothes on the body retard decomposition by excluding the air. Similarly, bodies placed in air-tight lead or zinc coffins resist putrefactive processes for a long period. Moist air favours putrefaction by diminishing evaporation, while dry air retards it. In the same way still air helps putrefaction, and air in motion retards it.

22. *Sucha Singh v State of Punjab*, AIR 1951 Shimla 283.

In the present case the body must have been in dry air and for not more than half the time at a temperature of over 70°F. The cause of death is certainly a factor in favour of the argument for the appellant as regards putrefaction, since at p 133 Mr. Modi has observed that putrefaction is hastened after death occurring from asphyxia; but even so, it cannot be denied that the general conditions favoured the slow development of putrefaction and were entirely different from those in which the development is at all rapid.

One other point relied on for the appellants was that some dark fluid blood was found by the doctor whereas normally one would expect the blood to have coagulated. It is, however, stated at p 520 of Vol 1, 10th edition of Taylor's *Principles and Practice of Medical Jurisprudence* that in case of death from asphyxia the blood is found fluid for an usually long time after death and it coagulates very slowly, owing amongst other factors to the excess of carbonic acid gas contained in it, and for the same reason it is very dark in colour.

In the circumstances, the statement of the doctor, which should not have been allowed to pass unchallenged by the prosecution or by the learned Sessions Judge, is not a sufficient reason for rejecting the whole of the prosecution evidence and it should be said that evidence as a whole amply establishes the guilt of both the accused.[22]

23.14.17 Rigor Mortis[23] (TOD)

1. This was the statement by the doctor who performed the post-mortem examination at 10 am on the 25th February that the time between death and the post-mortem examination was 24 to 48 hours. According to this statement, which seems to be a general expression of the opinion based on the fact that *rigor mortis* was still present in the legs and that decomposition has not yet set in, the prosecution case, as it stands, is that the murder took place about 61 hours before the post-mortem examination, whereas the statement of the doctor would set it at the extreme limit of 48 hours and it has, therefore, been seriously contended that on the basis of this statement alone it must be found that the whole prosecution case is a fabrication. If the statement were to be taken as literally true, it would no doubt put an end to the prosecution case, but actually the statement is only an expression of opinion which might have been modified if proper questions had been put to the doctor. No questions were put to the doctor in an effort to get him to qualify this estimate of the time of death. It would seem that the persons responsible for the conduct of the trial in the lower court were not properly applying their minds to the facts of the case, since if they had been, they would have at once realised the effect of the doctor's statement on the prosecution case and put further questions to him on the point. The counsel for the accused, of course might well have been content to let matters rest where they were.

Before dealing with the condition of the body as described by the doctor, it is necessary to describe, so far as they can be ascertained, the conditions under which the body is alleged to have remained lying undisturbed from the evening of the 22nd to the early afternoon of 24th February. The official tables disclose that during the period the temperature at the place ranged between a maximum of 80°F. The body was left under a shady tree, and it is unlikely that the body, at any time while it was lying at the spot, was for any considerable period exposed to the rays of the sun if at all.

The first point relied on by the counsel for the appellants was the doctor's statement that some signs of *rigor mortis* were still present in the legs. Regarding *rigor mortis*, J.P. Modi, in his textbook: *Medical Jurisprudence and Toxicology* at p 120 of 9th Edn., states:

23. *Sucha Singh v State of Punjab*, AIR 1951 Shimla 283.

> *The time of onset varies greatly in different cases, but the average period of its onset may be regarded as three to six hours after death in temperate climates, and it may take two or three hours to develop, and as regards duration in temperate regions,* rigor mortis *usually lasts for 2 to 3 days, though it may last several days, 9 days according to Casper, and three weeks according to Taylor. In Northern India, the usual duration of* rigor mortis *is 24 to 48 hours in winter and 18 to 36 hours in summer.*

This passage appears to be the principal basis of the doctor's estimate of the time between death and the post-mortem examination in the present case, and great reliance is also placed on it by the appellant's counsel. It is, however, clear from the subsequent remarks of Mr. Modi that it is hard to fix any definite limit. For instance, the deceased was about 17 years of age, and at p 121 Mr. Modi states:

> *Age*:—In adolescent and healthy adult bodies the occurrence of *rigor mortis* is slow, but well marked, while it is feeble and rapid in the bodies of children and old people.

As regards the manner of death, he says that *rigor mortis* sets in early, and disappears soon in deaths from diseases causing great exhaustion and wasting of the muscles, as in cholera, plague, typhus, typhoid, phthisis, cancer, uraemia and chronic Bright's disease but its onset is delayed in deaths occurring from pneumonia, *apoplexy*, asphyxia and nervous diseases causing paralysis of the muscles. Perhaps most important, he further states as regards atmospheric conditions, that *rigor mortis* commences slowly, but lasts for a longer time in dry, cold air.

Regarding muscular condition, he says that the onset is slower, and the duration longer, in those cases where muscles have been healthy and at rest before death than in those cases where the muscles have been feeble and exhausted, and thus have lost a greater degree of muscular irritability.

It may be mentioned that the deceased is described by the doctor as well built young man. Thus, all the conditions in the present case, including the age, muscular condition and cause of death, as well as the climatic conditions, clearly favoured the late onset and long duration of *rigor mortis*, and in the circumstances it is not impossible that the post-mortem examination may have taken place 60 or 61 hours after the death in spite of the presence of *rigor mortis* in leg.[23]

23.14.18 Development of *Rigor Mortis*[24]

The first contention of learned counsel for the appellants is that Gurdip Singh had actually died at about 3-4 am on 12 June 1990 and his dead body was brought to the house and thereafter, with due deliberations and consultations, the case was planted against the appellants and others by ascribing all of them specific roles, as have been narrated while giving details of events as given by Mohinder Singh, the first informant with a view to prop up the contention, noted above, reliance is placed upon the testimony of P.W. 5 Dr. K.S. Babbar and, in particular, the cross-examination, adverted to him where he stated that it takes 12 hours during which *rigor mortis* develop in all four limbs, and they remain intact for next 12 hours and thereafter they start disappearing and take about 12 hours to disappear completely. He also stated that as *rigor mortis* were found in the four limbs of deceased Gurdip Singh, the death was more than 12 hours before when postmortem was conducted. It may be recalled that as per the prosecution version, the occurrence took place at about 6-6.30 am on 12 June 1990, and post-mortem on the dead body of Gurdip Singh was conducted at 3.30 pm on the same day. Inasmuch as about ten hours had elapsed when the doctor had conducted post-mortem on the dead body of Gurdip Singh, he must have died far before six-sixth.30 a.m. and the time can well be pinned down to 3-3.30 am on 12 June 1990, contends the learned counsel. We have given our thoughtful consideration to the contention of the learned counsel, noted above, and

24. *Mangal Singh v State of Punjab*, 1996 Cr LJ 3258.

find that there is no substance in it. In our view, the opinion expressed by Dr. K.S. Babbar, P.W. 5, with regard to *rigor mortis* is not correct. Modi, in his book titled '*Medical Jurisprudence and Toxicology*' 18th Edn., at p 121 opined as follows with regard to *rigor mortis*:

> *Time of on-set*: This varies greatly in different cases but the average period of its on set may be regarded as three to six hours after death in temperate climates and it may take two to three hours to develop. In India, it usually commences in one to two hours after death and takes one to two hours to develop.....In Northern India, the usual duration of *rigor mortis* is twenty-four to forty-eight hours in winter and eighteen to thirty-six hours in summer. According to the investigations of Mackenzie in Calcutta the average duration is nineteen hours and twelve minutes, the shortest period being three hours and the longest forty hours. .....Cases have occurred in which rigor mortis developed and disappeared within an hour and a half after death.

Taylor, in his book titled *'Principles and Practices of Medical Jurisprudence'*, Vol I, 12th Edition, at p 83, states that "*rigor mortis* usually commence within two to four hours of death, though they may not become evident until five or seven hours have passed". To this general statement, there are numerous exceptions, some of which can be explained by physical facts. The example given by him is as under:

> *In the case of R.V. Aloott (Survey Assizes, 1952) a young man was found stabbed to death in a Railway booking office. When he was first examined, one hour after the crime,* rigor mortis *was absent, two hours later, however, it was complete. The deceased had fought the attackers vigorously before receiving a fatal wound.*

Layon in his book tiled '*Medical Jurisprudence for India',* at p 144, comments as follows:—

> *Niderkorn found it to be fully developed before the end of the seventh hour after death in 92 out of 113 cases (Tidy, Leg Med. IP 62) Taylor (3rd Edn., 1888, I. 513) gives 5 to 6 hours from death for* rigor mortis *to set in 16 to 24 for its continuance or 21 to 30 hours from death on an average. Tidy gives 3 to 6 hours from 36 to 48 hours respectively or 27 to 54 hours from death on average. But in sudden death in a muscular subject from hemorrhage* rigor mortis *may continue for 14 days or long (Gidy Leg. Med. I, 71).*

From the expert opinion of the Authors, mentioned above, we are the view that the opinion given by Dr. K.S. Babbar P.W. 5 that as *rigor mortis* were found in the four limbs, the death was more than 12 hours before post-mortem is incorrect. That apart, the prosecution is supported by four stamped witnesses and if their presence is either not disputed or is proved, the opinion of the doctor would pale into insignificance.[24]

23.14.19 Cause of Death[25] (Compression)

The post-mortem examination was held on the 12 December 1952 at 9 am. On dissection of the body, the civil surgeon found a patch of ecchymosis 3" in diameter on the left side of the chest over the second and third intercostal space along the mammary line. The injury has caused a fracture of the third rib and the chest bone near it (sternum) attached to the third rib. In the opinion of the civil surgeon the injuries on the chest resulting in the fractures were ante-mortem injuries and were caused either by blows with a hard and blunt substance or by applying heavy pressure on the chest.

The doctor explained that the injuries on the chest could be caused by putting the weight of one's body on to the chest of the deceased woman while the latter was laying down, either through the hands or by using one knee, thereby leaving no external marks in injury on the chest. The doctor was definitely of the opinion that the old woman died as a result of shock caused by the injuries on her chest.

The defence of the appellant was that the old woman died a natural death and the appellant was falsely implicated.

---

25. *Kutuhal Yadav v State of Bihar*, AIR 1954 SC 720 : 1954 Cr LJ 1802 (SC).

The learned Sessions Judge found first that Musammat Sobha had not died a natural death but had died as a result of the injuries caused on the chest resulting in the fracture of the third rib and the sternum. He further found that the circumstances proved against the appellant were such that the only reasonable inference was that the appellant had caused the injuries on the chest of the old woman on the night of the 10 December 1952 which injuries had caused her death. He held that the circumstances proved against the appellant were incompatible with his innocence, and found the appellant guilty of murdering the old woman and of attempting to cremate her dead body in order to cause the disappearance of the evidence of the offence committed by him.[25]

23.14.20 Cause of Death[26] (blunt weapon, not drowning)

The villagers searched for the body of the deceased but could not find it. Later on, the body was found by the sub-inspector in a canal about half a mile from the place of occurrence. The body had been eaten by tortoises and the head and the face were bitten off and the skin had dropped off. The eye lids were absent. The post-mortem examination was held the next day at about 1 P.M. The visible injuries on the body consisted of a contusion 2 × 3″ on the left shoulder and another contusion 1 × 1″ on the right shoulder. Soft tissues of head and neck were absent. There was fracture of right parietal bone.

In the brain there was clotted blood in an area 4 × 4″ on the right lobe of the cerebrum. The membranes were congested with petechial haemorrhage. In the opinion of the doctor, who performed the post-mortem examination, death was due to coma following the injury on the head. The doctor in his statement in court stated that the head injury could have been caused by one blow or by more than one blow and that death was due to head injury and not to drowning because there was not much bloating and the deceased had not sucked in a large amount of water.[26]

23.14.21 Cause of Death Crowd attack[27]

Mr. Sankunni appeared on the spot and the attack was launched by A. 4. All those who followed his lead and took part in the attack were certainly acting with the intention to do a criminal act. When such a large crowd armed with sticks as those produced in court attack a single man, stones being thrown at him, certainly that assembly must have known the consequences of such act also, especially in view of the specific statement the previous day at the meeting at A.4's house. So none of those who took part in that attack can escape from the consequences of the combined action of the riotous crowd. As to the offence committed against the deceased, the defence contention is that it at the most can only be hurt. It is pointed out that the nature of the injuries mentioned in Ex. O proved and spoken to by P.W. 11 will lead only to that conclusion and that if the death was caused by Mr. Sankunni, it was not due to the injuries sustained in the attack, but only because medical aid was given to him very late in the day. P.W. 11s evidence shows that the injuries noted in Ex. C were serious. In Ex. O itself his opinion is noted down. Here there is the fact that the deceased was left in the spot in a disabled condition and there was premeditation regarding the assault. The assault was by a large crowd armed with sticks and stones. There was previous expression of an intention to murder persons like the deceased. In the face of this the defence cannot escape by saying that if Mr. Sankunni had died of the injuries they cannot be fastened with the liability of the consequences that followed their action. Of course there has been a delay in giving medical aid. It is sad to reflect that a police officer was left in that spot for so many hours within a few miles of a police station and

26. *Behari v State of Uttar Pradesh*, AIR 1953 All 203 : 1952 All LJ 546 : 1953 Cr LJ 565 (All).
27. *Chiramel Varied Devassikutty v State of Travancore-Cochin*, 1953 Cr LJ 1301 : AIR 1953 Trav-Co 275.

a town where medical aid was available and within an hour's run from the central headquarters of the police as well as the division inspector's headquarters and even though accompanying the deceased person and information was conveyed to the highest police authorities within half an hour of the incident. But this fact cannot help the defence.[27]

23.14.22 Cause of Death[28] (Punctured Wound)

Appellant Ishwar Singh was however found guilty under section 302 simpliciter of the Indian Penal Code for the murder. Chauhal Singh died of shock and haemorrhage due to the sharp puncture wound on his chest caused, according to Dr. A.P. Mathur, Additional Civil Surgeon, Meerut, who conducted the post-mortem examination "some sharp edged pointed weapon". He added that the wound "might have been caused with a *ballam*". But whose hand was it that dealt this fatal blow with a "sharp edged pointed weapon". P.W. 1 Mahabir, P.W. 2 Satyapal, P.W. 6. Ram Rikh and P.W. 7 Jait Singh have all repeated that it was Ishwar Singh who struck Chauhal Singh with a *ballam*. But for the reasons we have already given implicit acceptance of their evidence is not possible and one must look for independent corroboration of the fact. The evidence of sub-inspector Karam Chand (P.W. 8) is that a *ballam* was recovered from Ishwar Singh's house, and a *bhala* from Harpal's. Dr. Mathur who said that the fatal injury "might have been" caused by a *ballam*, admitted on cross-examination that he did not know the difference between a *ballam* and a *bhala*. By *ballam* he meant "such weapon as is sharp edged on both sides, pointed, and less than 2 cm. in width" and he added that "if a *bhala* is of this very shape this injury is possible." It is not disputed that *ballam* and *bhala* are weapons of a similar type. Had the doctor seen the weapons seized from the houses of Ishwar Singh and Harpal, it might have been possible for him to say which of them caused the injury. But the weapons seized were not shown to the doctor. In *Kartarey v State of Uttar Pradesh*, AIR 1976 SC 76 (80-81) this court emphasised the importance of eliciting the opinion of the medical witness who had examined the injuries of the victim:

> It is the duty of the prosecution, and no less of the court, to see that the alleged weapon of the offence, if available, is shown to the medical witness and his opinion invited as to whether all or any of the injuries on the victim could be caused with that weapon. Failure to do so may sometime, cause aberration in the course of injustice.

In this case it is impossible to say with certainty whether the injury was caused by the *ballam* or the *bhala* that were seized. Therefore, whether it was Ishwar Singh or Harpal who was responsible for it even if one believed that on the day of the occurrence, former carried a *ballam* and the latter a *bhala*. Ishwar Singh's conviction under section 302 of the Indian Penal Code cannot be sustained in these circumstances.[28]

23.14.23 Accident, Suicide or Murder[29]

Now this medical officer in examination-in-chief said that the injuries could not have been caused by a simple fall from an elevation. On this evidence, the prosecution presses hard for maintaining the conviction of the accused. There would have been some strength in this reliance of the medical evidence if the medical officer had stuck to his statement in examination-in-chief and had not conceded probabilities which completely fitted in with the defence suggestion. In cross-examination he has said that, if the hammer was made to stand on one end, the injuries 1 and 5 could be possible by a fall from a height of 7 or 8 feet. Again, he repeated that those two injuries could be possible by a fall on the hammer if it was kept lying flat. The hammer was sent for and we have seen it ourselves. It is a big and heavy one,

28. *Ishwar Singh v State of Uttar Pradesh*, 1976 Cr LJ 1883 : AIR 1976 SC 2423 : (1976) 4 SCC 355.
29. *Jalwanti Lodhin v State of Bihar*, AIR 1953 Pat 246 : ILR 32 Pat 217 : 1953 Cr LJ 1344 (Pat).

therefore, I am not in a position to say that the statement in cross-examination of the medical officer was made out of some other consideration. Again, the witness has stated that a fall on the cemented floor could cause the fracture of two or three ribs. It is in evidence of one of the prosecution witnesses that the floor was actually a cemented one (*vide* the evidence of P.W. 1). Looking at the injuries, it appears to me that injuries Nos. (1), (5) and (6) which were all on the left side, could be caused by one blow, direct or indirect, and injury No. (4), which was also on the left side, could be the result of injury No. (1). The prosecution has no explanation how the deceased could get an incised wound on the head and a fracture of the second or the third rib if the accused had struck the deceased on the head only with a hammer. There is a difference between incised wounds and incised-looking wounds. In this connection I may state that the sub-inspector found a drum containing lime with bloodstains on it, which were found by the state serologist to be of human origin. This incised injury could not have been caused, to my mind, by a blow of the hammer which has been produced in this case. The prosecution has not been able to give any explanation how the two ribs of the unfortunate woman could be fractured if she was sleeping peacefully on a cot when she was murderously attacked with a hammer. Accordingly, the medical evidence does not fully support the prosecution; rather, the injuries do not at all rule out the possibility of those being caused by a fall from an elevated place.[29]

23.14.24 Reconstruction: Murder or Suicide[30]

The City Inspector Rameshwar Kumar Sharma, P.W., had also arranged to get the dead body in the closet photographed from Gurcharan Singh, Photographer, P.W. 9, and two Photographs, Exhibits p 1 and p 2, along with their negatives, are also on the record. These photographs were admitted by all the four accused. From photographs. Exhibits p 1 and p 2, it is quite evident that the dead body was placed just at the threshold of the door which was the entry of the closet. The dead body appears to have occupied the entire breadth of the store. The head and the back of the dead body were raised against the wall in such a position that the body could not fall. It also appeared that the legs could not be stretched beyond the opposite wall. In this closet were also found various household articles including drums, From a look at the photographs when perused with the statement of the doctor, which has been reproduced above, it becomes crystal clear that the right side of the dead body except the portion just towards the upper right thigh in contact with the mattress on which the dead body was seated had not been burnt. The blouse on the right side except for a few burnt portions was intact. According to the doctor, the blue colour of the blouse had not been affected. The petticoat or the sari cloth on the left leg seems not to have been burnt. All the tell-tale burnt marks were on the left arm, left shoulder, left chest and the left side of the face and head. All the articles lying in the store near the dead body do not seem to be disturbed. At point D in photograph, Exhibit p 1, some article appears to be in close contact with the left side of the dead body, but none of the articles appears to have been disturbed. Plastic bangles on the right arm also do not appear to have been at all burnt. A close look at the second photograph, Exhibit p 2, which was taken by the photographer from the back, shows that the left upper arm and the left shoulder are completely burnt mass and below the elbow nothing is observable. Towards the left of point B and the right of point Y there appears radius which in the opinion of the doctor was jutting out from the elbow joint in a completely burnt condition. There does not appear to be anything below figure Y. The doctor was exhaustively cross-examined at this point by the trial court. In reply to one question, it was stated that the left arm up to the elbow was so much burnt that there was no flesh left and the bones were charred to ashes. In reply to another question, it was clarified that "the burnt bones turned to ashes just like remains left after the cremation." It was

30. *Kuldip Sham v State of Punjab*, 1980 Cr LJ 71.

also deposed that only the upper two-thirds portion of the radius and ulna were jutting from the elbow joint and the rest had fallen off. In reply to another question, it was stated that the rest of the portion was missing. However, after the statement had been completed, the doctor, before signing the statement, without the order of the court and without bringing the same to the notice of the court, himself added the word "not" thereby showing "the rest of the portion was not missing."

A close perusal of the statement of Dr. G.D. Chawla, P.W., leaves strong impact on the mind that it was his clear statement in the first instance that the portion below the elbow joint of the left arm was missing and had been completely burnt to ashes. Subsequently, however, he made a deliberate attempt to wriggle out of it and to make equivocal statement that some bones were jutting out of the elbow joint.

According to the trial court, the burns on the dead body of Usha Rani, deceased, were not ante-mortem and that one-third portion of the left arm below the elbow was missing before the dead body was put to fire and the same was done in order to conceal the injuries which may have been inflicted on that part before her death. It was also opined that the doctor had not dissected the head and the face from which also correct opinion could be formed if some injuries had been inflicted on the said parts of the body. The doctor, however, categorically stated that the burns on the dead body of Usha Rani were ante-mortem in nature and were sufficient to cause her death in the ordinary course of nature. Though it is not possible to form a categorical opinion from the material on the record if the burns on the dead body were ante-mortem or post-mortem in view of the categorical statement of the doctor, yet from the oral evidence of the witnesses who had seen the dead body lying in the closet, as referred to above, the two photographs and the statement of the doctor, no doubt, is left that even if it was a case of death by fire and the consequential burns the body of Usha Rani had not been subjected to fire in the closet and that the dead body was placed therein only after death. If Usha Rani had caught fire whether accidentally or intentionally to commit suicide, after the body caught fire, she must have writhed with pain and made frantic movements of hands and legs and the natural consequence would be that the articles lying near the dead body must have been disturbed. Besides the wall, the door and the threshold where the body was seated or was in contact must have also borne the impact of fire and the smoke. At least, the rice lying in the *thali* could not but show signs of the impact of intensive fire. It is clear from the photograph, Exhibit p 1 that a cloth is covering the dead body which did not have any sign of fire or even smoke. Indisputably, this cloth had been put on her after she had died. Even according to Mohan Lal, CW, who had just followed Ram Lal, accused, after Shanti Devi, accused, had raised hue and cry, he did not see any person had seen the closet. Thus, the only conclusion possible is that Usha Rani was already dead whether by fire or otherwise when her dead body was placed in the closet.

After having arrived at the above conclusions, the conduct of Kuldip Sham, accused, assumes considerable importance as in a case based only on circumstantial evidence, the conduct of the accused is also an important link in the chain of incriminating circumstances to arrive at the correct conclusion. According to the statement of Kuldip Sham, accused, after the close of the prosecution evidence, he used to go for a morning walk every day and on 28 March 1976, had gone for a walk at 6.15 am along with his partner and friend, Dharam Vir Mahajan, CW 1. At that time, his wife Usha Rani was quite fit and alive. When he returned at about 6.45 am he found a crowd of people having collected in front of his house. It was then that he came to know that Usha Rani was dead and her dead body was lying in the closet, he further stated that Usha Rani had died by sprinkling kerosene oil on her body and then putting herself on fire after he had left the house for a walk in the morning. This defence version stands completely negatived and contradicted by the convincing evidence and the objective circumstances on the record. As discussed above in the closet, but her dead body had tragic end. Even Mohan Lal CW, who

had immediately followed Ram Lal, accused on hearing the cries, did not see any sign of fire or smoke coming out of the closet at any time in the morning. The version of the accused that he had gone for a morning walk with Dharam Vir Mahajan, CW, was also belied by the deposition of the latter as a court witness (CW 1). According to his deposition, he did not even know Kuldip Sham, accused, and had not gone with him for a morning walk. This conduct of the accused in fabricating a story that he had gone out of the house in the morning and that it was in his absence within a short span of half an hour or so that his wife Usha Rani committed suicide is a strong indication of his guilty mind and a deliberate attempt on his part in order to conceal the commission of offence. If it were Kuldip Sham, accused, and Usha Rani who had slept in the house on the relevant night, and Usha Rani had for one reason or the other, committed suicide or had died by accident, it was not probable that Kuldip Sham, accused, would concoct such a cock and bull story. The relations between the two being strained and Kuldip Sham being aggrieved against his wife whether on account of the non-fulfilment of his demand for more dowry or because he suspected her fidelity on account of the seizure of the letter addressed to her by some other person, the dead body of Usha Rani found in the closet in suspicious and mysterious manner and the deliberate attempt on the part of the accused to concoct a false story are such incriminating circumstances from which no other conclusion is possible except that it was Kuldip Sham, accused, who was instrumental in committing the murder of his wife by putting her on fire or in any other manner. It has been held in *Deonandan Mishra v State of Bihar*, AIR 1955 SC 801 : 1955 Cr LJ 1647 : (1955) 2 SCR 570, that in case of a murder when there is no direct evidence and the prosecution case is based only on circumstantial evidence, absence of explanation or false explanation by the accused serves as an additional link in the chain of circumstances to connect the accused with the offence. In the present case, as discussed above, the accused, Kuldip Sham, came out with a statement in explanation regarding the cause of death of his wife which has been found to be palpably false.[30]

23.14.25 Number of Assailants[31]

The deceased was a healthy person and 30 years of age and according to the post-mortem report had received 22 injuries in various parts of the body with a sharp edged weapon, while two injuries had been caused with a blunt weapon. In the opinion of the doctor these two injuries could also be caused by a fall on a hard substance.

If the statements of the eye-witnesses had been correct, and if it were true that all the three were giving the beating then there would have been a sufficient number of injuries caused by *lathis* as well. The medical evidence discloses that the two accused who practically played no part, while Phoola who was armed with a sharp-edged weapon, was busy inflicting the injuries all the time. Where an interested witness makes a verbal statement as regards the existence of certain facts, and it is possible for the court to put it to a test in the light of checks available on the record, it should not be easily accepted unless it is corroborated and stands the test. The important check available in this case consists of the post-mortem report and since it shows almost all the injuries inflicted with sharp-edged weapons, the statements of the witnesses, that all the accused were inflicting injuries when they saw them, cannot be accepted as true and must be rejected as false.

23.14.26 Oral v Medical Evidence: Resolution[32]

If the medical evidence is believed, it is clear that seven persons could not have participated in this crime. Where there is a conflict between the medical evidence and the oral testimony

31. *Abdul Salam v State of Jammu and Kashmir,* 1953 Cr LJ 1865 : 10 J&K LR 94.
32. *Thakur v State of Uttar Pradesh*, AIR 1955 All 189 : 1955 Cr LJ 473 (All).

of witnesses, the evidence can be assessed only in two ways. A court can either believe the prosecution witnesses unreservedly and explain away the conflict by holding that the witnesses have merely exaggerated the incident or rely upon the medical evidence and approach the oral testimony with caution testing it in the light of the medical evidence. The first method can be applied only in those cases where the oral evidence is above reproach and creates confidence and there is no appreciable reason for the false implication of any accused. Where the evidence is not of that character and the medical evidence is not open to any doubt or suspicion, the only safe and judicial method of assessing evidence is the second method.[32]

23.14.27 Skeletal Remains[33]

1. It is obvious that, in order to bring home guilt to the accused, the prosecution must affirmatively establish that the human remains exhumed in this case were those of the deceased Sellayee. If that fails, it would obviously be most unsafe to act upon the retracted judicial confession, even if we believe that the confession might have been voluntarily made, and that it does contain elements of truth. For it is a fundamental maxim of the criminal jurisprudence administered in this country, that suspicion and conjecture cannot take the place of legal proof.

If there is any possibility, even apart from a probability, that Sellayee might turn up alive from the Nilgiris tomorrow, or some future date, the accused cannot be convicted of this murder. That possibility can be excluded only upon adequate evidence of the *corpus delicti*. In the present case that inference is sought to be established upon the report of the chemical examiner (Exhibit p 16A), containing the opinion of an expert and the identification of the piece of saree (MO 1) and the torn jacket (MO 2) and perhaps also upon the discoveries made in pursuance of information given by this appellant from the river bed, the wig or false hair (MO 7) and the bead necklace (MO 3).

Now we desire to emphasise that, whatever might be the situation in law with regard to proof of a report of a chemical examiner or other expert such as (Exhibit p 16A), where that report not merely contains the result of a laboratory test, like the presence of human bloodstains, but also contains the opinion of an expert upon inspected material, such as bones or part of a skeleton, it is certainly the duty of the prosecution to examine the expert, and not merely to rely upon the report. The public prosecutor at the trial should certainly have examined. Dr. Asiryadham, the expert, instead of merely contenting himself with marking the report. We have now rectified this lacuna by ourselves examining Dr. M. Asirvadham, B.A., M.B.B.S., Ph.D., F.C.A.P., Professor of Forensic Medicine, Madras Medical College, whose opinion was the basis of the report.

His explanation is sufficient to show that it would be most unsafe to base the identification of the remains exhumed in this case upon his expert testimony. Dr. Asirvadham is clear that the bones were most probably of those of a female aged between 16 and 20 years, from the bones of the pelvic girdle examined by him, as well as the epiphyses of the shoulder bones. But he is not even clear that all the bones must necessarily relate to a single individual. Referring to the cuts noticed in the bones (items 3 and 4) he is not at all certain that they must necessarily have been caused ante-mortem.

The account of the murder in the judicial confession, Exhibit p 5, was read out to him, and he is not at all certain that the account inevitably fits in with the data revealed by his expert scrutiny of the bones. Apart from this, it is obvious that no reliance can be placed upon the piece of cloth or jacket (MOs 1 and 2). For P.W. 1 himself told the police that, in the absence of any specific marks, he could say nothing about the identification. There is another

33. *Marudai Prisoner (re),* AIR 1960 Mad 370 : 1960 Cr LJ 1102 (Mad).

important point. Several bones were missing including the entire skull. The account in Exhibit p 5 is that the head was severed, and separately buried a short distance away, in the same river bed.

Why were the skull bones never recovered by the police? As regards the bead necklace (MO 3) and the wig (MO 7) they are articles which could have belonged to any poor woman of the lower classes and admit of no identification whatever. Dr. Asirvadham concedes that the cuts found in the bones could have been caused post-mortem during burial or exhumation by the sharp edge of a spade, In brief, it is impossible to conclude that the bones exhumed were those of Sellayee, or that the *corpus delicti* has been established.

23.14.28 Dry Bone after 4 days of murder unlikely[34]

The first point for consideration before the jury was whether Kalaram was actually dead and whether his death has been conclusively proved by the evidence on record. Next comes the question of the culpability of the accused. The learned judge tentatively suggests that the bones might not have been those of Kalaram because there were no identifying marks but he does not say what is to be inferred if the bones are wrong bones. Neither does he say that this is an essential point on which the jury should come to a decision.

The learned judge says that he read out the medical evidence to the jury but surely he did not ask them to apply their minds as to whether the bones of a man murdered only four days ago could have been found in the condition in which they were found by the doctor who held the post-mortem examination rather a scrutiny over the bones. Nobody speaks about any foul smell nor of any decomposed human matter lying about near those scattered bones which were seized by the police from inside a jungle. The bones were dry and clean they bore no marks of flesh. Most of the bones were dismembered from the trunk and the greater part of the human body was missing including a skull. In other words, there were some disjointed pieces of human bones dry and devoid of flesh. The glaze in the bones had disappeared and the ends were all rough. There was no sign of ante-mortem injury on the bone.

The members of the jury undoubtedly had a right to think about this and they could have judged for themselves whether the bones of a man murdered on the 16th could have been in this condition on the 20th or 21st of April on which date the post-mortem examination was held. The witness going to the locality from where these bones were collected did not say that there was any foul smell in the locality or there were fermented blood or decomposed human materials near about the place. The evidence of the investigating officer is that the place from which this dead body and the clothes were seized were at a distance of 15 feet from the road and the prosecution evidence is that men used to pass that way from Malaibari to Khetri and nobody complained that there was any foul smell during those days even earlier to the bones being seized. In case the jury had come to the finding that these bones were bones of some other person lying dead, they might have equally suspected the identity of the clothes which were lying there about as said by P.W. Govinda. It is well-known that if a material part of the prosecution story is found to be false or fabricated, the jury would be entitled to doubt the genuineness of the rest of the story or doubt the prosecution case itself. This was obviously such a factor to which the judge ought to have directed the attention of the jury and this omission is a material misdirection which in my opinion vitiated the charge.

34. *Tirtha Bahadur Bhojal v State of Assam*, 1955 Cr LJ 782 : AIR 1955 Assam 107.

23.14.29 Recovery of bones does not identify the victim[35]

It was contended by Mr. Rajabalan that mere recovery of 22 human bones from a pit in a town like Davangere will not lead to an inference that those bones are the bones of Motimala. The fact that M.Os. 11 and 12 were found in the pit, which was full of water and which was exposed cannot be disputed in view of the evidence of P.W. 32, the C.P.I., the panch witness P.W. 21, N.B. Basanur, and P.W. 28 the wife of the deceased. It was contended by Mr. Rajabalan that human body consists of more than 200 bones and on this basis he contended that the recovery of only 2 bones would not lead to an inference that the bones recovered were those of Motimala. Taking into consideration the state of affairs and the condition of the pit in which the clothes and the bones were found, (the possibility of some bones having been dragged away by dogs or vultures cannot be ruled out). The 22 bones recovered were undoubtedly human bones and that is the evidence of P.W. 31, Dr. Ramu, associate professor of Forensic Medicine. Then what should have happened to the remaining bones? The only irresistible conclusion is that the other bones must have been dragged away by dogs, vultures, There is indisputable evidence which establishes that the 22 bones that were found in the pit must be some of the bones of the dead body of Motimala. The two clothes namely M.Os. 11 and 12 have been identified as belonging to Motimala. A-l has not given any rational explanation how and under what circumstances he had the knowledge that the clothes belonging to Motimala and the bones were in the pit. With regard to the seizure of M.Os. 11 and 12 and the bones M.O. 9 there cannot be any dispute because the property form under which these articles were seized shows that they were produced before the magistrate on following day, and orders were obtained for retention.

Corpus delicti means first that a crime has been committed, that is to say that man is dead and that his death has been caused by a crime. But it is understood that the dead body itself is not *corpus delicti*. If the crime has been committed and if the dead body is not found or traced, the person who committed the crime cannot be permitted to contend that because the dead body is not available, he is not liable to be punished. What is necessary in cases of this nature is that it must be positively established that the man was murdered, and whether or not the dead body is available, if the other evidence supports the commission of the crime, the accused could be convicted. One does not begin to enquire whether the accused is guilty of a crime until one has established that a crime has been committed. Regard must be had not only to what is intended to be done but how it is attempted. If the crime is established, whether or not the dead body is found, the accused could be convicted. The circumstances mentioned above conclusively establish that Motimala was alive on 17 June 1969, who in the ordinary course, would have returned to Bombay but in fact did not return as expected, but on the other hand, what is established in this case is that two of his clothes identified by P.W. 28 were found in the pit along with 22 human bones. This fact conclusively establishes that Motimala must have been a victim of a foul play on or about 17 June 1969.

In support of the above fact, there are a number of other circumstances to probabilise the case of the prosecution. The same day on which information was given A-l, the remaining clothes of Motimala were recovered from the hut of A-l at Davangere. If Motimala, as contended by Mr. Rajabalan, was alive, he would not in the ordinary course have left his clothes in the house of A-l and gone away. All the clothes that were brought by Motimala from Bombay to Davangere were either found along with the human bones or in the hut of A-l. The facts stated above, therefore, clearly point out to the only conclusion that Motimala was done to death on or about 17 June 1969.

35. Re *Surchand Ramji Chavan*, (1972) 1 Mys LJ 297 : 1972 Mad LJ (Cri) 196 : 1972 Cr LJ 1108 (Mys).

23.14.30 Unidentified Skeleton No evidence[36]

The skeleton was sent to the Central Forensic Science Laboratory for examination and report and Ex. P.W. 18/A is the report in regard to the said skeleton. The report states that the skeleton was of a human being and the skull had four prominent injuries. The report also says that injuries marked A and B on the skull could have been caused with the *dranti* but no opinion could be given in regard to the other injuries.

The identity of the human skeleton is sought to be proved by the evidence (a) that two front teeth in the upper jaw and two front teeth in the lower jaw were missing and (b) that the clothes found on the skeleton were of the deceased Jai Ram. In the report Ex. P.W. 14/A Shanti had given the following description of Jai Ram, age 58/59 years, wheatish colour, stout and healthy body, height about 6 ft., broad forehead, broad face, one front tooth of upper jaw missing, grey hair on the head, wearing a *khaddar kurta* of almond colour and a *dhoti*, and an ordinary *jutti* (shoes) in his feet.

The Director, Central Forensic Science Laboratory in his report only found that the skeleton was of a human being. No medical opinion was obtained as regards the age, sex or estimated height of the human being whose skeleton it was. There is also no evidence that the bones belonged to one individual. A medical expert on an examination of the bones could have given opinion as to the age, sex and estimated height of the person to prove that the skeleton was of the deceased Jai Ram, but no effort was made to obtain such an opinion. P.W. 3 Sher Singh, brother of the deceased, gave evidence that he identified the skeleton as that of his brother Jai Ram from the missing teeth and the shirt and the dhoti. P.W. Tara Chand made a similar statement. P.W. 7, Jai Narain gave evidence that he used to stitch the clothes of Jai Ram and he can identify the *kurta* p 2 which was stitched by him for Jai Ram. In cross-examination he stated that he was not asked by the sub-inspector to identify the *kurta* but he had done so on his own, that he had not put any mark of his own on the *kurta* when he stitched it. P.W. 8, Ram Kumar stated that he identified the skeleton as of Jai Ram by the broken teeth in the upper and lower jaws.

We saw the clothes in the court and in our view the clothes, in the state they are, were not capable of identification. Clothes like p 2 are a common wear and it would be wholly unsafe to fix the identity of the skeleton on such evidence. The wife of Jai Ram was missing. The identification by P.Ws. 1, 3 and 8 of the skeleton from the broken teeth in the upper and lower jaws are also not convincing on the facts of this case, in our view, it cannot be said beyond doubt that the human skeleton recovered was of Jai Ram.

The skeleton was recovered from an open place which was accessible to all even if it be believed that the skeleton was recovered on the information given by Joginder Singh accused, the possibility that he may have come to know from some other source of a dead body having been buried at that spot cannot be ruled out. In any case, no conviction under sections 302 and 364 could be founded on the solitary piece of evidence that a human skeleton was recovered at the instance of Joginder Singh, even if the skeleton is held to be that of Jai Ram. At best the offence against Joginder Singh would be one under section 201 of the Penal Code and the sentence awarded to him under section 201 was one year which he had already undergone.[36]

23.14.31 Age by Radiography[37]

1. But there is a greater infirmity which strikes at the root of the order. It is alleged in the petition that detenue was a minor aged about 17 years at the time of arrest and detention and

36. *Joginder Singh v State of Delhi*, 1975 Cri L J 233 (HC).
37. Jaya mala v Home Secretary J&K, AIR 1988 2 SC 1297.

that it is difficult to even conceive that this school going minor boy would indulge into such activities as to be a serious threat to the maintenance of public order. In para 7 of the petition it is alleged that the detenue was not even 17 years of age at the time of his detention. In the return filed on behalf of the State, the only assertion is that this averment is misconceived and needs no reply. But in para 2 of the return under the heading paragraph-wise reply it was denied that the detenue was a minor and it was further averted that his age was between 18 and 19 years. In support of this averment reliance was placed upon report as to the age issued by Dr. T.R. Sharma attached to Government Medical College, Jammu, Dr. Sharma appears to have examined the detenue for ascertaining his age by radiological and orthopaedic test on 3 May 1982. The relevant portion of the report reads as under:

> *Epiphysis around ankle, wrist, elbow and shoulder joints have appeared and completely fused. Epiphysis for iliac crest has appeared and partially fused. Radiological age is between eighteen and nineteen years.*

Detenue was arrested and detained on 18 October 1981. The report by the expert is dated 3 May 1982, that is nearly seven months after the date of detention. Growing in age day by day is an involuntary process and the anatomical changes in the structure of the body continuously occur. Even on normal calculation, if seven months are deducted from the approximate age opined by the expert, in October, 1981 detenue was around 17 years of age, consequently the statement made in the petition turns out to be wholly true. However, it is notorious and one can take judicial notice that the margin of error in age ascertained by radiological examination is two years on either side. Undoubtedly, therefore, the detenue was a young school going boy. It equally appears that there was some upheaval in the educational institutions. This young school going boy may be enthusiastic about the students' rights and on two different dates he marginally crossed the bounds of law. It passes comprehension to believe that he can be visited with drastic measure of preventive detention. One cannot treat young people, may be immature, may be even slightly misdirected, may be a little more enthusiastic, with a sledge hammer. In our opinion, in the facts and circumstances of this case the detention order was wholly unwarranted and deserved to be quashed.[37]

23.14.32 DOB Records or Radiography[38]

The learned trial Judge has taken into consideration the discrepancy found in the date of her birth as recorded in her school record as transpiring from her school leaving certificate at Ex. 7. Therein her birth-date is recorded as 15 August 1968. When the more reliable proof of her birth-date is available in the form of an extract from the birth register, it is not necessary to rely on the birth-date recorded in her school register, more particularly when the difference is hardly of 34 or 35 days. It is possible that at the relevant time the age of a child to be admitted to school was relatable to the cut-off date of 31st August, If her birth-dates as found in the extract of the birth register at Ex. 8 was taken into consideration, she could not have been admitted to school on account of the cut-off date of 31st August. If her birth-date as found in the extract of the birth register at Ex. 8 was taken into consideration, she could not have been admitted to school on account of the cut-off date of 31st August of the concerned year. It is not uncommon that the birth-date of a child is advanced to a certain extent with a view to saving one precious academic year. It is possible that, in order to admit the child to school to save her precious one year, the birth-date of the child was required to be advanced in such a manner as to fall within the cut-off date of 31st August. That appears to be the reason why in the school record her birth-date was shown to be 15 August 1968 and not 19 September 1968 as found in the extract of the birth register at Ex. 8.

38. *Gujarat v Inayathusen Mahmadmiya*, 1996 Cr LJ 3225.

We know that conjectures, hypotheses and/or surmises have no play in the criminal trial as such. We also know that no explanation has been brought on record by or on behalf of the prosecution with respect to the discrepancy of the birth-date recorded in the extract from the birth register at Ex. 8 and the school leaving certificate at Ex. 7. Since the difference found is of 35 days only, we have permitted ourselves to travel in the realm of conjectures, hypotheses and surmises. This is based on human behaviour and conduct as is commonly known. With respect, the learned trial Judge has made no attempt to explain away such discrepancy. Besides, as indicated by us hereinabove, the birth-date recorded in the birth register maintained by a local authority like the Municipal Corporation of Ahmedabad would furnish a more reliable proof of the age of the child mentioned therein rather than the birth-date recorded in her school register. We are of the opinion that the extract of the birth register at Ex. 8 would prevail over the school leaving certificate at Ex. 7 so far as the birth-date of the girl in this case is concerned. In this view of the matter, we have to accept the birth-date as recorded in the document at Ex. 8 and it is 19 September 1968. She was therefore aged 14 years 10 months and 23 days on the date of the incident.

We are supported in our view by the Division Bench ruling of the Kerala High Court in the case of *Krishnaranjan v Doraswamy Chettiar*, AIR 1966 Ker 305. It has been held therein that entries in the birth register furnish the best evidence of the date of birth and can safely be accepted unless they are shown to be wrong. It has further been observed therein that birth entries in the registers of public schools, though relevant under section 35 of the Evidence Act, 1872, are of far less evidentiary value and of little avail to show the correct age of the person concerned. We are in respectful agreement with the aforesaid principle of law enunciated by the Division Bench of the Kerala High Court in its aforesaid ruling in the case of *Krishnaranjan* (supra). The aforesaid Division Bench ruling of the Kerala High Court cannot and need not be distinguished on the ground that it was rendered in a civil case and not in a criminal case. What has to be culled out from its reading is the principle of law it has enunciated.

23.14.33 Medical Evidence[39]

Ordinarily, the value of medical evidence is only corroborative. It proves that the injuries could have been caused in the manner alleged and nothing more. The use which the defence can make of the medical evidence is to prove that the injuries could not possibly have been caused in the manner alleged and thereby discredit the eye witnesses. Unless, however, the medical evidence in its turn goes so far that it completely rules out all possibilities whatsoever of injuries taking place in the manner alleged by eye-witnesses, the testimony of the eye-witnesses cannot be thrown out on the ground of alleged inconsistency between it and the medical evidence.

The main ground on which the evidence of the eye-witnesses have been discarded by the Sessions Judge, as observed belied the prosecution case. The High Court, in our opinion was fully justified in coming to the conclusion that medical evidence did not belie the prosecution case, rather it was in support of the prosecution case. In the view that the High Court took about the medical evidence, it proceeded to consider the worth of the evidence of the eye-witnesses. In the opinion of the High Court all the three witnesses were possible witnesses and their presence was quite natural. P.W. 4, being the widow of the deceased was likely to be present at home and see the incident herself. P.W. 3 was also the grand-daughter of the deceased. Her presence at house is also a likely one. The third witness was a neighbour. The evidence of P.W. 4 was sought to be challenged on the ground that in her deposition before the police she had not named P.W. 3, the grand-daughter of the deceased as present at the time of the occurrence and the evidence of P.W. 3, the grand-daughter who was aged seven years or eight years, was

39. *Solanki Chimanbhai Ukabhai v State of Gujarat,* AIR 1983 SC 484 : (1983) 2 SCC 174 : 1983 Cr LJ 822.

sought to be discarded on the ground that her name was not given by P.W. 4 in her statement before the police. The High Court has dealt with both these criticisms and has rightly come to the conclusion that all the three witnesses were natural witnesses and were present at the place of occurrence. The High Court has discussed the evidence of these three witnesses at great length and has also considered the grounds on which the testimony of these witnesses has been discarded by the Sessions Judge. It has given cogent reasons for relying on the testimony of the three witnesses. No exception, in our opinion, can be taken to the appraisal of the evidence made by the High Court.

23.14.34 Circumstantial evidence[40]

The deceased, a minor girl aged about 8 years, had gone to attend the 'Mela' along with her younger brother. It is the case of the prosecution that the appellant who is aged about 50 years then, took away the deceased from the 'Mela' and committed raped and murdered her. The father informed the police stating that his daughter, who had gone to attend the 'Mela', has not returned home. Upon such complaint, the case was registered and investigation commenced. It was the case of the prosecution that in the process of investigation, Investigating Officer found a headless body of the deceased in the bushes. During the process of investigation, the statement of the appellant was recorded and the blood stained clothes and articles he used for the offence were recovered from his house.

It is contended by learned counsel for the appellant that though there is no acceptable and convincing evidence to prove the guilt of the accused beyond a reasonable doubt, the appellant is convicted by the trial court based on the circumstantial evidence which is not enough to record guilt of the accused. It is submitted that from the evidence on record, the prosecution has also failed to prove the concept of 'last seen'.

The Court has observed that the brother of the deceased who has accompanied the deceased to 'Mela' on the fateful day. He has identified the accused in the Test Identification Parade and further he has categorically stated that the appellant took away the deceased from the 'Mela'. Further, PW-1 has deposed that when he was coming from his shop to the residence, he saw a dog running away with a leg of a child in its mouth and on being chased it dropped the leg. Further investigation revealed detection of headless body of the deceased in the bushes. Further, PW-7 has also stated that he had seen the appellant on the fateful day at 9.00 pm with a girl wearing a yellow frock. By applying the 'last seen' theory to the facts of the case and further considering the forensic and medical evidence on record, trial court has rightly recorded guilt of the accused for the offences alleged and the High Court, referring to the relevant evidence on record, has rightly confirmed the conviction of the appellant for the charges levelled against him.

23.14.35 Judges as Medical Expert[41]

The High Court has opined that the extensive injury No. 2 found on the deceased could not have been caused with a weapon like a *pharsa*, but with a weapon having a long curved blade. Here also, the learned judges were not on *terra firma*. *Pharsa* is a sharp-edged weapon. We are told its blade resembles a *gandasa* blade or may even be curved like that of a battle-axe. The *pharsa* or the weapon with which the fatal injuries were caused has not been recovered. This argument therefore, rests on imaginary premises. The best person to give an opinion about

40. *Nand Kishore v State of Madhya Pradesh,* AIR 2019 SC 3310.
41. *Raisul v State of Uttar Pradesh*, AIR 1977 SC 1822 : (1976) 4 SCC 301 : 1977 Cr LJ 1555 (SC). **Also see**: *Arshad v State of Andhra Pradesh*, 1996 Cr LJ 2893 : 1996 (3) Andh LD 410; *Ambika Prasad v State (Delhi Admn.)*, AIR 2000 SC 718 : (2000) 2 SCC 646 : 2000 Cr LJ 810.

the nature and shape of the weapon of offence used, was the medical officer (P.W. 4) who had conducted the autopsy. The doctor (P.W. 4), as already noticed, testified that the injuries found on Panchania (deceased) could have been caused with a *pharsa* or some other sharp edged weapon.

Dr. Bhuneshwar Prasad (P.W. 3) also, who had examined the child, Jai Devi testified that the injuries found on the child had been caused with "some sharp-edged weapon including a *pharsa*". The High Court was thus clearly in error in substituting its own opinion resting on conjectural premises for that of the medical experts regarding the nature of the inflicting weapon.[42]

It is true that the learned Sessions Judge on looking at the appellant thought that he must not be less than 24 years of age, and the High Court also, on seeing the appellant personally, took the view that the estimate of age given by the Sessions Judge was correct, but we do not think that the learned Sessions Judge as well as the High Court were right in substituting their own estimate in regard to the age of the appellant and on the basis of such estimate, rejecting the statement as to his age made by the appellant. Appearances can often be deceptive. We must, therefore, proceed on the basis that the appellant was below 18 years of age when he committed the offence.

23.14.36 Improper Appreciation of Medical Evidence[43]

The most important question that requires consideration in this appeal is whether the accused appellant did not suffer any injuries in the hands of the assailants who had committed the murder of the deceased Shashivandanaben but such injuries had been suffered by the accused appellant either on account of self-inflicted injuries or on account of injuries caused by a friendly hand. For basing the conviction, the learned third Judge and the Sessions Judge have held that the appellant did not suffer injuries on her head or on the eye by the assailants who had committed the murder of the deceased. But such injuries were either by way of self-inflicted injury or by a friendly hand in an attempt to give an appearance that the appellant was also attacked by the assailants who had committed the murder of the deceased. It is not in dispute that the acused was removed to Vadilal Hospital along with the deceased and the accused was admitted as an indoor patient in the said hospital. The accused was examined by the doctor in the hospital, namely, Dr. Virendra S. Manek (P.W. 3) at about 12.25 midnight on 25 October 1979 in the Emergency Ward of the hospital and the following injuries were noted on the person of the accused:—

1. C.L.W. ½″ × ½″ × ¼″ curved shape on the left parietal occipital region.
2. C.L.W. 1″ × ½″ × ¼″ on the left parietal region posterior to above injury.
3. C.L.W. 1″ × ½″ × ¼″ curved shape on the left parietal occipital region.
4. C.L.W. 1″ × ½″ × ¼″ on the right parietal region posteriorly.
5. C.L.W. 1″ × ½″ × ½″ over occipital region irregular in shape. Bone deep.
6. C.L.W. 1″ × ½″ × ½″ over occipital region anterior to above injury No. 5.
7. C.L.W. ½″ ½″ ¼″ over right parietal region anterior part.
8. There was sub conjunctival haemorrhage on the left eye.

42. *State of Uttar Pradesh v Shanker*, AIR 1981 SC 897 : 1980 Supp SCC 489 : 1981 Cr LJ 23 (SC).
43. *Tanviben Pankaj Kumar Divetia v State of Gujarat*, AIR 1997 SC 2193 : 1997 AIR SCW 2055 : 1997 Cr LJ 2535.

Dr. Manek has indicated that all the said injuries were possible by a blunt object. There was no fracture of the scalp bone. The doctor also noted that there was also bleeding at the occipital region when he had first seen the injury. The accused was kept as an indoor patient in the same hospital and was discharged from the hospital on 31 October 1979. It may be stated here that the infant child of the accused aged about six months was also examined in the hospital and the following injuries were noted on the person of the infant:

1. One abrasion ½″ × ¼″ over the right side of forehead.
2. There was diffused round swelling size ½″ × 1″ over the forehead.
3. There was soft tissue swelling on frontal region which was found on X-ray.

The doctor has stated that the abrasion found on the forehead of the infant child was possible by contact with a blunt object and the same could also be caused by a fall. So far as the swelling injury of the child was concerned, the doctor has stated that such swelling might be the manifestation of the internal injury.

Dr. Manek has categorically stated that the injuries sustained by the accused could not be self-inflicted. In this connection, Dr. Manek has stated that there are five layers over the head of the skull and if the injury is bone deep, it can be said that the five layers have been penetrated. The doctor has further stated that he apprehended that the said injury on the eye was likely to be on account of injury on the anterior cranial fossa which was part of the base of the skull. No fracture of the skull, however, was found after X-ray was taken. Dr. Manek has also stated that skull wounds normally bleed very freely. For the purpose of giving treatment to the accused, her hairs were shaven and at that time, bleeding of about 20 or 25 cc of blood had taken place. It has also come out in the evidence of P.W. 4 Dr. Dilip Hargovandas Shah that the accused was brought in the emergency ward and thereafter Dr. Desai had given stitches on the wounds of the head of the accused.

In this case, the expert opinion of Dr. Shariff as to the nature of the injuries suffered by the accused was sought for by the prosecution. Opinion as to the probable time of death of the deceased after receiving injuries was also sought. The said Dr. Shariff was requested by letter (Ex. 24) by the Superintendent of Police Force (Crime Branch) to give his expert opinion the following points:

1. Please scrutinise the P.M. Notes and state as to at about what time the deceased might have died.
2. Whether the deceased would have died on the spot looking to 21 injuries on her person as mentioned in P.W. Note.
3. What is your expert interpretation about the term "Defence incised wound."
4. Kindly refer to the medical certificate of Smt. Tanviben P. Divetia.
5. State whether these injuries could be self-inflicted.
6. Looking to the injuries on the person of Tanviben whether it was necessary to admit her as an indoor patient.
7. Whether the injuries found on the head of Smt. Tanvi Divetia could be inflicted by giving blows with the hammer.

Dr. Shariff by his letter dated 17 March 1980, gave his opinion on the said queries after going through the injury report of the accused and the post-mortem report of the deceased and also in-patient record of accused Smt. Tanviben and out-patient record of the accused. Although Dr. Shariff has given his opinion that the injuries suffered by the accused were simple in nature, he has admitted that since the injuries were found on the head of the accused, the

hospitalisation of the patient was desirable for observation and treatment. Dr. Shariff has also opined that the injuries on the head of the accused were not consistent with the injuries usually caused by hammer but he has also stated when cross-examined by the learned counsel for the accused, that he had not seen any hammer before giving any opinion and without seeing the hammer, definite opinion could not be given. He has also stated that by the expression 'hammer,' he meant hammer of considerable size and he admitted that he did not understand the difference between '*hathodi*' and '*hathoda*'. He has also stated that it was dangerous for a person to cause injury by himself or herself on the head and agreed that in respect of some injuries of the accused little more force might have resulted in fracture of skull. Dr. Shariff has also stated that Modi's *Medical Jurisprudences* is one of the standard books but he disagreed with the view expressed by Dr. Modi in Modi's *Medical Jurisprudence and Toxicology* that contusion and lacerations on the head could rarely be self-inflicted. But Dr. Shariff has agreed with the view that contused or lacerated wounds could rarely be caused on account of the pain they are likely to cause and the force required to produce them as indicated in the Textbook of *Medical Jurisprudence and Toxicology* by Dr. C.K. Parikh. Dr. Shariff has also stated that superficial injury means the injury situated on or near the surface. When his attention was drawn that injury No. 5 suffered by the accused is extended up to bone and whether such injury can be stated to be superficial injury. Dr. Shariff has stated that such injury has not been stated to be superficial by any authority and he may have to find out some authority in support of his view that such injury is superficial and he has also added that the opinion was given by him on the basis of his own experience. He has also admitted that he has not seen the report of the radiologist and also the X-ray plate of the accused.

So far as the sub-conjectival haemorrhage on the eye of the accused is concerned, Dr. Shariff has stated that sub-conjectival haemorrhage was likely to be the result of direct blow in or around the eye and he has agreed that normally a person could not cause an injury on the eye by oneself and he has also not come across any case of self-inflicted injury on the eye. He has also agreed that the injury on the eye was not on account of self-inflicted injury. He has also admitted that from the case papers of the accused there was nothing to suggest that haemorrhage was an old one. Dr. Shariff has also stated that severe blow by hard and blunt substance had resulted in such injury. Dr. Shariff has also stated that injury found on Tanvi could be caused by hard blunt substance.

In our considered view, the expert opinion of Dr. Shariff that the injuries of the accused were self-inflicted or caused by a friendly hand should not be accepted. It is quite evident that the accused had sustained multiple injuries on her head and one of such injuries was bone deep and if a little more force was used in causing the said bone deep injury, the skull might have fractured. Dr. Manek who had examined the accused, has clearly stated that such injuries could not be self-inflicted. It is the specific case of the accused that she was hit on the head by '*hathodi*' meaning thereby a small hammer like object, Dr. Shariff has specifically stated that he had given his opinion that the injuries could not be caused by a hammer on the footing that a heavy and big hammer had been used. It is also quite clear that the accused had suffered the eye injury on account of severe blow by a blunt object and it had been stated by Dr. Manek that such injury cannot be self-inflicted injury. Such a view has also been expressed by Dr. Shariff. It may be stated here that Dr. Manek had actually examined the accused and had noted the injuries himself, but Dr. Shariff gave his opinion only on the basis of the injury report and the X-ray report without even looking to the X-ray plate. In such circumstances, we are inclined to rely more on the opinion of Dr. Manek than on the opinion of Dr. Shariff. We are also of the view that the injuries caused on the eye of the accused and also one of the injuries on the head were quite serious and it was highly improbable that the accused would invite such injuries to be caused by a friendly hand. We may also indicate here that the infant baby aged only six months had also suffered injuries and the doctor has given opinion that the

abrasion suffered by the infant was possible by contact with a blunt object and could be caused by a fall and the diffused swelling found on the infant reflected the manifestation of some internal injury. In our opinion, it is also highly improbable that such injuries could be caused on the infant of six months either by the accused herself who was mother of the child or she would allow anybody to cause such injury voluntarily to give a show that infant along with herself had been attacked. On the contrary, the nature of the injuries suffered by the infant fits in with the statement made by the accused indicating the manner in which the infant was dealt with by the assailant thereby causing the injuries on the child. On a careful consideration of expert opinion and the evidence adduced regarding the injuries suffered by the accused and the infant child, we have no hesitation to hold that such injuries suffered by the accused and the infant were neither self-inflicted nor caused by any friendly hand.

So far as to the probable time of death of the deceased after receiving injuries is concerned, Dr. Shariff has given an expert opinion that the time of the death of the deceased was 10 or 12 hours prior to the time of the post-mortem examination which was held from 7.30 to 9.30 am next day. If the deceased had been attacked some time after 8.30 pm on the previous night then according to the opinion of Dr. Shariff, the probable time of death of the deceased was about 6.30-9.30 pm being 10 to 12 hours prior to the post-mortem examination. Dr. Shariff has based his opinion only on the basis of post-morterm report and notes on post mortem report and also taking into consideration the presence of *rigor morits*, lividity, coolness and the report of injuries found on the person of the deceased. Dr. Shariff has stated that common carotid bifurcates into internal and external carotid and he had indicated that he had presumed that common carotid was cut looking to the words 'carotid artery' used in post-mortem report. The doctor who actually held the post-mortem examination, has specifically stated that carotid was not completely cut and injury was situated on the posterior aspect of the carotid but Dr. Shariff did not agree with such view by noting to the words 'carotid artery' in the post-mortem report. Dr. Shariff has also deposed that in the out patient case papers, it was mentioned that the body of the deceased was cool when she was examined in the hospital but he has admitted that there was no mention of body temperature of the deceased in the case paper and he has also deposed that the mention of coolness must have been made by touching the body. Dr. Shariff has also stated that in the post mortem report, there was no mention of atmospheric temperature, humidity and movement of air. He has admitted that without assessment of these factors, proper estimate of the time for setting of *rigor mortis* cannot be given. He has also stated that *rigor mortis* was only a rough guide for determining the time of the death and he has also agreed that onset of *rigor mortis* will be quicker if the muscles are feeble and exhausted and that in case of cut throat injury, *rigor mortis* sets in early. It is, therefore, quite apparent that in the absence of various factors which had not been noted by any doctor considering which the probable time for onset of *rigor mortis* and estimation of probable time of death with reference to the state of *rigor mortis* and coolness of the body can be fairly estimated, any opinion as to the time of death therefore cannot be held to be wholly reliable. We may also indicate here that the doctor who had held the postmortem examination had occasion to see the injuries of the deceased quite closely. In the absence of any convincing evidence that the doctor holding post-mortem examination had deliberately given a wrong report, his evidence is not liable to be discarded and in our view, in the facts of the case, the opinion of the doctor holding post mortem examination is to be preferred to the expert opinion of Dr. Shariff .[43]

23.14.37 Digestion Time Variable[44] (Not Proper Guide to Time of Death)

We have given our thoughtful consideration to the submissions made at the Bar and have with the assistance of learned counsel for the parties examined the judgments of the courts below as also the material evidence in the case.

44. *Mani Ram v State of Rajasthan*, AIR 1993 SC 2453 : 1993 AIR SCW 1885 : 1993 Cr LJ 2530.

We are in agreement with the High Court that the evidence of P.W. 1 Surjeet Kaur and P.W. 2 Jaskaran has not been viewed and considered in the correct and proper perspective by the trial court and undue and unwarranted emphasis had been attached to certain minor discrepancies. Our independent appraisal of the evidence of both the witnesses P.W. 1 and P.W. 2, the widow and son of the deceased, shows that they are consistent in their versions not only about the assailants but also about the manner of assault, as has been noticed by us in the earlier part of this judgment. Both the witnesses have given a vivid description of the occurrence. The statement of P.W. 1 Surjeet Kaur that Hazur Singh took his meals at about 10.30 am and that the occurrence had taken at about 12-12.30 in the noon cannot be taken to have been contradicted by the medical evidence. Indeed, in the post-mortem examination, Dr. K.C. Mittal P.W. 9 found semi-solid undigested food in the stomach of the deceased. The doctor opined that digestion begins in 1 or 1-one-second hours. From this testimony what was sought to be made out by the defence was that had the occurrence taken place at 12.30 noon, the deceased would have had his meals before 11-00 a.m. as semi-digested food was found in the stomach of the deceased. The emphasis on this aspect of the case by the trial court, in our opinion misplaced not only because the medical evidence is only an evidence of opinion and hardly decisive but also because when Dr. K.C. Mittal P.W. 9 stated that digestion begins in 1 or 1-one-second hours, he did not clarify as to what was the extent of the undigested food in the stomach of the deceased. The process of digestion depends upon the digestive power of an individual and varies from an individual to an individual. It also depends upon the type and amount of food taken. The period of digestion is different for different types of food. Some food articles like mutton, chicken would take more time of being digested compared to vegetarian food. No question at all were asked from the wife of the deceased about the type of food served to her husband or the amount of food taken by the deceased. That apart, the time stated by the witnesses as to when the deceased took his food was only an approximate time as it was not even suggested to P.W. 1 that she had a wrist watch and had actually seen the time when her husband took his food. Too much play on such slippery factors goes against realism and is not enough to discredit the otherwise reliable testimony of P.W. 1. In our opinion, the evidence of P.Ws. 1 and 2 does not stand contradicted by the medical evidence at all and as a matter of fact, the presence of semi-solid undigested food in the stomach lends support of the testimony of the two witnesses that they had gone to the field later on with the food for the deceased and had actually served meal to him. It lends assurance to their presence in the field with the deceased. Despite the lengthy cross-examination, nothing was brought out in the cross-examination of either of these two witnesses which could affect the veracity of their testimony. The first information report was lodged by Surjeet Kaur. P.W. 1 at 3.00 pm at a distance of about 15 miles from the place of occurrence and was therefore lodged with great promptitude and the entire version of the occurrence finds mention in that report. The testimony of both the witnesses has impressed us and they appear to us to be truthful witnesses and being the close relations of the deceased would, in the ordinary course of things, be the last persons to screen the actual offender and implicate the appellants falsely. Their testimony also receives ample corroboration from the medical evidence and the testimony of ballistic expert Shri G.R. Prasad P.W. 11.

Dr. Mittal P.W. 9, as already noticed, found six injuries on the deceased and opined that the same were sufficient in the ordinary course of nature to cause the death. In the FIR Ex. p 1 lodged soon after the occurrence P.W. 1 Surjeet Kaur had stated that Mani Ram appellant had fired 3-4 shots after he had fired the first shot on her husband. At the trial, she however, could not state exactly as to how many shots had been fired by the appellant from his pistol. That is not surprising because she could not be expected to keep an exact account of the shots fired by the appellant, when she found her husband being shot at and having fallen down dead. She categorically attributed the gun shot injuries to the appellant and did not attribute

any injury to the acquitted accused Hari Ram. Since, it has been found that the recovered empties had been fired from the pistol of the appellant, it lends sufficient corroboration to her testimony. We may ignore the testimony of Sukh Ram P.W. 4 as a matter of abundant caution but that would not in any way detract from the reliability of the testimony of P.W. 1 and P.W. 2.

The pistol, weapon of offence, was taken into possession from the appellant by P.W. 6 SHO Bhim Singh. It is a licenced pistol of the appellant. According to the evidence of ballistic expert P.W. 11, the empty cartridges sent to him for examination had been fired from that pistol and that pistol alone and from no other similar weapon. Of course, the sealed packets containing the pistol and the cartridges were sent to the ballistic expert after a long delay and that could have created some doubts about the possibility of substitution of the cartridges, while the packets remained with the police but the evidence on the record rules out any possibility of such a substitution. The three sealed packets, one, containing pistol, the second, containing the empty cartridge recovered from the spot and the third, containing the three empty cartridges recovered from the appellant along with the pistol, were deposited in the *malkhana* of the police station. They had been received by Head Constable Mani Ram P.W. 10 on 23 June 1972, the very next day after the occurrence. He had sent the same to the police lines at Ganganagar. The prosecution examined P.W. 12 Amar Singh who had carried the three packets from the police station to the police lines at Ganganagar. He categorically stated that while the packets remained with him, they were not tampered with at all. P.W. 10 Mani Ram also deposed that during the period, the sealed packets remained in the *malkhana*, they were not tampered with by anyone and that they were handed over to Amar Singh P.W. 12 in the same condition. According to P.W. 7 Ram Chandra, he received the three packets from Amar Singh and after taking them into custody he made an entry in the register and that while the packets remained in his custody, nobody tampered with them. The packets were sent to the ballistic expert and received there by Jaswant Singh P.W. 8 and Manraj Singh. Jaswant Singh, appearing as P.W. 8, deposed that he delivered the packets to the ballistic expert on the very next day after receiving them and while the packets remained in his custody, nobody tampered with them. According to the ballistic expert, P.W. 11, the packets when received by him were properly sealed and the seals were intact and tallied with the specimen of the seal sent to him. None of these witnesses were at all cross-examined. No suggestion even was made to anyone of them that the sealed packets had allegedly been tampered with while in their custody. No such suggestion was even made to SHO Bhim Singh P.W. 6 that he had either substituted the cartridges sent to the ballistic expert or otherwise tampered with the sealed packets. It is, therefore, futile to contend that the possibility of the substitution of the cartridges could not be ruled out. There is no basis for such an argument. The evidence of the ballistic expert, Shri G.R. Prasad P.W. 11, read with the medical evidence of P.W. 9 and the testimony of the eye-witnesses P.Ws. 1 and 2 clearly establishes that the appellant had fired from his licenced pistol at the deceased and that the deceased died as a result of the pistol shot injuries received by him. We agree with learned Judge of the High Court that there are no suspicious features at all appearing in the evidence which may cast any doubt on the prosecution version that the deceased was shot at with the pistol by the appellant and that he died as a result of the injuries so received.[44]

23.14.38 Doctor's Unprofessional Conduct[45]

We need to take note of the fact that in this as in all other rape cases there are not going to be eye-witnesses nor are there going to be witnesses to the actual incident. Invariably the

45. *State of Karnataka v Rangaswami*, 2003 Cr LJ 607.

Court is required to accept or reject the testimony of the victim and if the evidence is good enough, it is usually supported by the medical evidence and forensic evidence. In the present case, the evidence of PW-5 Jayamma is not supported by PW-I because he has given totally non-committal evidence and it is clear that he has been won over. Jayamma's evidence is very clear with regard to the aspect of identifying the four accused. It is also very clear about the fact that pursuant to their common intention she was held down by the accused persons and two of them raped her. She has also stated that the bite injuries on her breast were sustained in the course of this incident. The real difficulty that has arisen in this case arises from the fact that PW-12 Dr. Sujatha in her evidence states that Jayamma had complained of an attempt to rape and not actual rape. Whereas Dr. Ashalatha accepts the position that Jayamma had complained of having been raped. The doctors in this case, obviously because Jayamma is a poor villager, did not seem to have evinced the requisite interest nor have they acted responsibly and professionally as one would expect in a case where there is a serious charge of rape. The manner in which they have conducted themselves is cavalier, to say the least, and the same is the manner in which they have given evidence before the Court. Thanks to this totally disinterested and non-professional attitude that the Court is left with virtually zero assistance from the medical evidence. We do expect that the members of the medical profession and particularly doctors who are working in the public hospitals should grasp the seriousness and the horrifying consequences of the offence of rape and other sexual assaults and that they should act with a far more professional, responsible and considerate manner. The fact that such an incident took place is bad enough and the fact that because of this type of handling in the hospitals the Courts are forced to acquit the accused is compounding injustice and it is high time that the medical profession realises the damage that it is doing and acts in the manner which the law and the Courts expect of them.

This Court has found that time and again, the medical evidence in almost every case of sexual assault on women is tampered with and that the doctors come out with evidence that can only be termed as "pro-accused". It does not require much intelligence to see through these malpractices which clearly indicates that there is a very serious integrity problem at this level. We have come across instances where the doctors have brazenly given evidence that has virtually sabotaged the prosecution case as has happened in this instance and we wish to appeal to the conscience of each of these doctors, assuming they possess one, that it is because of what is happening in the hospitals that 94% of the rape cases in this State are ending in acquittals. We do not propose to close our eyes to this state of affairs and direct the Government to immediately formulate adequate safeguards to ensure that there is a full-stop to these illegalities.

24.14.2 Judicial Activism in a Rape case 1417
24.14.3 Age of the Rape Victim 1418

24.1 INTRODUCTION

Common serious sexual offences are:

1. Rape
2. Incest
3. Unnatural offences
4. Exhibitionism
5. Sadism
6. Voyeurism — "Peeping Tom"
7. Frottage
8. Masochism
9. Transvestism
10. Fetishism

24.2 RAPE

In India, rape is one of the most serious offences. The victims sometimes cannot bear the sense of shame and commit suicide. Law (section 375 of the Indian Penal Code) also provides severe punishments — imprisonment and fine. The prison term can be even for life.

Legally speaking:

> a man is said to commit rape who, except in the case hereinafter excepted, has sexual intercourse with a woman under circumstances falling under any of the five following descriptions:
>
> ***Firstly,*** against her will;
>
> ***Secondly,*** without her consent;
>
> ***Thirdly,*** with her consent, when consent has been obtained by putting her in fear of death, or of hurt;
>
> ***Fourthly,*** with her consent when the man knows that he is not her husband and that her consent is given because she believes that he is the man to whom she is lawfully married;
>
> ***Fifthly,*** with her consent, when, at the time of giving such consent, by reason of unsoundness of mind or intoxication or the administration by him personally or through another of any stupefying or unwholesome substance, she is unable to understand the nature and of that to which she gives consent.
>
> ***Sixthly,*** with or without her consent when she is under eighteen years of age.
>
> ***Explanation*:**
>
> Penetration is sufficient to constitute the sexual intercourse necessary to the offence of rape.
>
> ***Exception:***
>
> Sexual intercourse by a man with his own wife not being under eighteen years of age is not rape.

In simple non-legal words, rape means forceful sexual intercourse with a female (other than his wife) by a person when:

1. the female is not willing, even if she is a harlot,
2. the consent obtained by coercion,
3. the consent is obtained by deceit or misrepresentation (posing as her husband or misrepresenting the act as medical treatment),
4. the victim is mentally deficient: imbecile or idiot,
5. the victim is under the influence of drugs or liquor,
6. the person is unconscious,
7. the victim is young — below the age specified in law (18 years), and
8. the penetration of male organ into the female parts incurs the offence. Complete penetration or emission of semen is not necessary to prove the charge.

24.2.1 Rapist

Rapists are of four types:

1. Social degenerates: Some individuals who enjoy extra-marital sexual intercourse without ill-feeling. They are the real criminals.
2. Sex maniacs: Some individuals, though ordinary most of the times, get fits of sex mania and commit acts for which they are often sorry later on. They need medical treatment or psychiatric treatment as their biology may be responsible to urge/push them on to commit the crime.

3. Misguided: Some misguided individuals suffering from venereal disease believe that intercourse with a virgin would cure their venereal disease. They rape young girls.
4. Sex starves youngsters living in cities.

24.2.2 Investigator's Role

It is easy to level a charge of rape against a person, but it is difficult to prove it. The number of cases is increasing. It is increasing further because of the changing social values, falling moral values and increasing psychological insensitivity: no compunction at the sufferings and pains of the victims.

The government has made strict laws in 2013, but it seems they have no deterrence effect upon the culprits. The investigator has to be more vigilant.

The investigator has to proceed systematically to collect proper evidence and to provide proper proof as in cases of rape; there are usually no eye-witnesses. It is complainant's statement *versus* the accused person's statement. Of course, circumstantial evidence (and hence scientific evidence) is available. As the culprit and the victim come in close contact, there is plenty of exchange of traces. If the case is handled early and efficiently, convincing irrefutable evidence should be forthcoming.

Two problems worry the investigator. First, the culprit often claims consent of the victim. Second, there are sometimes false allegations. He has to keep these aspects in mind while investigating.

24.2.3 The Victim

The victim is the most crucial source of evidence in rape cases. The evidence is of three types:

1. Knowledge of the occurrence
2. Medical evidence
3. Evidentiary clues

24.2.3.1 Knowledge

The occurrence is best known either to the victim or to the culprit. As culprit is not interested in conveying the information, the only source left is the victim. The victim is also reluctant, bowed down by shame and uninitiated legal processes. This knowledge has to be extracted through careful sympathetic interrogation so that the chaff can be separated from the grains. The following points must be kept in view:

1. Interrogate the female in the presence of another female.
2. Ascertain the movements of the victim before and after the occurrence.
3. Ascertain the familiarity of the accused with the victim.
4. Collect even minute details of the occurrence:
    a. Place of occurrence
    b. Route and mode of transport
    c. Time of occurrence
    d. How enticed?
    e. How attacked?
    f. Weapon, if any.
    g. Resistance offered, if any. How was it overcome?
    h. How long did the act last?
    i. Dialogue or other sound at the time? Screams? Threats? Inducements? Endearments?
    j. Any witnesses who may have seen the pair together before or after the act?

These may help to know the *modus operandi* of the culprit, which helps to link or de-link the criminal with other similar crimes.

5. How soon after the occurrence was the complaint made? And to whom?
6. Who persuaded the victim to go to the police?
7. Ascertain the character of the victim. Previous sexual contacts with the accused may indicate a motive.

24.2.4 Medical Evidence

Both the culprit and the victim carry vital evidence. They are lost with the passage of time. Their medico-legal examination should, therefore, be carried out at the earliest.

Consent of the adult victim for medical examination is required legally. If she is minor, parents or guardians are approached for the consent. An experienced female medico-legal expert carries out the medical examination. It ascertains:

1. Are injuries consistent with violent and forced rape?
   - Evidence of forced sex act
   - Previous sex experience
   - Torn hymen
   - Injured vulva
   - bleeding
2. **Resistance Injuries**: their location, number, and extent are noted/described. They are often found both on the culprit and the victim if the female is healthy and spirited. Both are checked for:
   - Bite marks
   - Scratches
   - Signs of beating
3. **Torn clothes:** they should be taken into possession.
4. **Stains:** on clothes, body, especially on thighs and private parts?
5. Disorder of hairs, clothes?
6. **Any pregnancy**? How old?
7. **Age. Physical health**.
8. **Disease:** is the victim suffering from any venereal disease?
9. **Smegma:** presence of smegma is useful clue. It can refute the charge of false rape. Absence of smegma does not prove rape.
10. **Capability:** some accused person profess impotence.

24.2.5 Evidentiary Clues

The investigator must collect all the evidentiary clues with the help of the doctor, including the following:

1. Vaginal secretion and swabs for semen.
2. Foreign hairs and fibres on the person of the victim.
3. Specimen pubic hairs from the victim.

4. Semen stains from the body.
5. Fingernail scraping which may carry fibres, hairs, skin, blood from the culprit. The evidence can link the culprit, with the victim and hence with the crime.
6. Age of the victim often assumes great importance. Medical evidence for the age of the victim is important. It should be ascertained. However, a birth certificate and school certificates also prove useful. If the victim is less than 18 years of age, consent of the victim does not have any sanctity.
7. All clothes of the victim worn at the time of occurrence. They carry semen, fibres and hair, bloodstains, saliva stain from the culprit. They also indicate the extent of bleeding.

   Sometimes they carry dust, dirt, plant materials from the scene, which help to corroborate the victim's statement.

24.2.6 The Culprit

The culprit, per Locard's principle of exchange, must also carry important evidence, similar in character to that of the victim. The evidence is medical, physical and knowledge of the occurrence. He should be contacted and got medically examined at the earliest with his consent.

24.2.7 Medical Evidence

The medico-legal expert collects clues like stains, injuries, and trace evidence from the person of the culprit on the same pattern as in the case of the victim. They must be processed properly so that their authenticity, integrity, and chain of custody are not disturbed.

Collection of the above evidence should be done at the earliest so that the evidence is not lost.

24.2.8 Physical Evidence

The culprit carries the following evidentiary clues on his person:

1. Vaginal fluid stains, bloodstains, semen stains on the penis, on pubic hair, on the area around the male organ and thighs and on clothes. Smears from the male organ from pubic hair, from the surrounding skin, should always be obtained.
2. Foreign hairs — especially in the private parts and intermingled with pubic hairs. The doctor should collect them for further investigations.
3. Fibres from the clothes of the victim are often transferred to the culprit. They are mostly on his clothes.
4. Stains of cosmetics (lipstick, cream, powder) on the person and clothes.
5. The fingernail scrapings may contain vaginal fluid, skin, fibres, and cosmetics from the victim.
6. Dust, dirt, flora or fauna from the scene, especially in outdoor case

Clothes worn by the culprit at the time of occurrence must be taken into possession. They carry stains, tears, hairs, and fibres, flora and fauna and their fragments and dust and dirt from the scene.

24.2.9 Oral Evidence

The IO acts to:

1. Get the version of the accused and compare it with that of the victim.
2. Verify culprit's *alibi*.

3. Fix time frame of his movements around the time of occurrence. Find out their correctness.
4. Ascertain the association of the accused with the victim. Previous meetings? Previous sexual inter-course?
5. Ascertain the reason for the presence of the accused at the scene.
6. Ascertain reputation of the accused, his social and marital status, previous crimes, if any.
7. Ascertain his associates.

24.2.10 The Scene

The crime scene is the most important source of evidence, physical clues and *modus operandi*. It, therefore, demands extreme care in its processing. A careful examination of the scene of occurrence is always done at the earliest. The investigator takes steps to:

1. Document the scene (Video clips, Photographs, sketches, and textual narration).
2. Collect evidence:
   a. Hairs, fibres, discarded papers, pieces of cloth, clothing, cigarette stubs, and buttons.
   b. Stains, smears.
   c. Marks: fingerprints, footwear marks, tyre marks, lipstick marks, marks of struggle
   d. Soil, dust, dirt as a control sample for evidence picked up by the culprit and the victim.
   e. Broken bangles, jewellery
3. Ascertain the layout. Could anybody observe the scene and occurrence? Could anybody hear the screams or voices from the scene?
4. Ascertain if there was any chance witness to the occurrence.

24.2.11 Gang Rape

Gang rapes were a rare phenomenon in olden days. The influence of western culture has gifted the evil to India also. Gangsters, group of sex-starved employs rowdy delinquents join hand and gang-rape unfortunate females of all ages, often finishing the 'job' with murders. The menace is increasing by the day in spite of the government's professed intentions to curb it. The victim is raped by one after the other. All are accomplices and are equally guilty.

> *In a recent brutal gang rape and murder case, there were five rapists and murderers. Session Judge sentenced four of them to death and the fifth being a minor was awarded the maximum punishment under the law (September 2013) . The SC maintained the sentence*[1]*. (CH)*

24.2.12 Attempted Rape

Attempt to commit rape is also a serious crime. Here the culprit does everything to accomplish the crime, but due to certain unforeseen occurrence, he fails to complete the act. Proof has to be provided. All evidence available with the victim, the culprit and the scene should be collected. In genuine case, as the victim is assaulted, there is ample evidence available. It is processed in the same way as in the case of rape.

1. It is a landmark case, in Nirbhaya. where Forensic Science has been used extensively for proof beyond a reasonable doubt by the trial court, the High Court, and the Supreme Court.

24.3 INCEST

Incest is sexual intercourse between persons of prohibited relationship. For example, a person cannot have sexual intercourse with his sister, daughter, granddaughter, mother and some others.

It is believed that the number of cases of incest is quite large in India. However, they do not come to light due to social inhibitions. The few cases which are exposed are treated legally like rape.

> *In a case, reported by the mother of the girl, father was involved in the incest. When the daughter was checked, she was found to be used to sexual intercourse. Vaginal swabs did not reveal any sperms. They indicated the presence of some silicone grease. It was found similar by infrared spectrophotometry, to the one found on the contraceptive sheaths recovered from the father. (CH)*

Investigation of incest follows the rape route.

24.4 HOMOSEXUALITY

Intra-sex, sex gratification is known as homosexuality. It is unnatural offences under Indian law. Section 377 of the Indian Penal Code deal with the offence:

> *Whoever voluntarily has carried intercourse against the order of nature with any man, woman, or animal, shall be punished with transportation for life or with imprisonment of either description for a term which may extend to ten years and shall also be liable to fine.*

Homosexuality exists in all societies, and perhaps it always existed. It is more frequent where persons are sex-starved. Sailors on the sea, students in boarding houses, and convicts in confinements (jails) practice homosexuality.

Homosexuality was considered a troublesome social problem previously. It is widespread. It is estimated that in the USA more than 4% of males are hard-core homosexuals. Homosexuality carried Stigma in days gone by, not now, extortionists blackmail homosexuals. In the USA in 1967, Federal Bureau of Investigation broke up a gang of 70 extortionists. Among their victims were some of the top rankers of the society — university professors, generals, and politicians.

Homosexuality has since been legalized in the USA and some other countries. Gay marriages have become legal. In India, there is serious thinking going onto legalise homosexuality after making section 377 null and void.

In India, there is a class of people called Hijrahs. They are eunuchs (transgender) — who are neither male nor female. They act as male prostitutes. They also steal young boys, castrate them, and put them for passive pederasty.

Homosexuality is of two varieties:

- Sodomy
- Lesbianism

24.4.1 Sodomy

Sex gratification through anal intercourse is called sodomy. It is also called buggery or paederasty. Sex act through the mouth, called fellatio or oral sex, may also be classed as a form of sodomy.

The passive agent may be an adult male, a young boy, a eunuch or even a female.

Sodomy may be by mutual consent. If it is so and if it is performed in privacy, it does not become a police problem for investigation. If, however, sodomy is carried out by force, or by deceit, or in public places, it becomes a police problem. The police investigation in such cases follows the rape case pattern. The types of evidence collected are:

1. The oral evidence of the victim and of the culprit. Usually, there are no witnesses.
2. Medical evidence from both the culprit and the victim.

3. Physical evidence associated with the act and picked up by the partners from the scene of occurrence or exchanged mutually.

In an unusual case a child of six was brought to the hospital with an injured anus. It was reported that the pet dog in a sudden frenzy climbed over the child and repeatedly introduced his sexual organ in the anus of the child. It was suspected that perhaps some member of the family in a moment of mental aberration might have carried out the act. The family might have concocted the story to protect the member of the family. The dog had allegedly been killed. The swabs taken from the anus revealed the truth: The dog had actually attacked the child. (CH)

The three sources for evidence are the victim (passive partner), the culprit (the active partner) and the scene. The evidence is located, collected and evaluated as in the case of rape, already discussed.

24.4.2 Lesbianism

Lesbianism is sexual interaction among females for sexual gratification. It is also known as tribadism or female homosexuality. It is less common. It does not appear as a police problem. Lesbianism comes to surface only when a male goes in for a divorce from his wife alleging her to be a lesbian.

Lesbianism takes many forms. It may be simple fiddling of the body parts especially private parts. It may be intercourse like attempt with clitoris if it is sufficiently enlarged. Or, it may be an artificial penis, used by one woman to gratify another or for self-gratification.

In an interesting case two women lived as husband and wife. The 'husband' had manly bearings and used an artificial penis. The 'wife' could know the fact that 'he' was a 'she' only after the latter's death. (CH)

24.5 BESTIALITY

Sexual intercourse with animals through vagina, anus or any other orifice, usually by a male is called bestiality. This sexual offence is not very common but it does take place. Usually, youths in rural areas and mentally deficient persons indulge in these sex acts. The animals reportedly misused are goats, cows, buffalos, mares, asses, bitches and even hens.

The proof of the act is usually established through eyewitness accounts and through scientific evidence, which may be as under:

1. Injury to culprit, animal or to both
2. Presence of semen or spermatozoa in the orifice or on the coat of the animal
3. Animal faeces on the male organ, private parts and/or on the clothes of the culprit
4. Animal hair on the person of the culprit
5. Detection of disease germs if the culprit is suffering from venereal disease, on the animal
6. Semen or semen smeared objects at the scene
7. Semen on the clothes of the culprit

Some women use dogs for the sex act.

24.6 EXHIBITIONISM

Certain persons derive sexual pleasure if they expose their sexual organs to the public or before certain individuals. Some of them may even masturbate in public. All these persons offend

the public by their indecent behaviour. They, therefore, are liable for punishments for causing public nuisance under section 294 of the Indian Penal Code.

The cases of exhibitionism do occur in India also but only a few and far in between.

24.7 SADISM

This is an unfortunate sexual perversion performed mainly by male sexual partners on the female partners. The mildest form of the disease is to carry out the sex act violently and the worst is to murder the partner and then carry out the sex acts. In between, the sadistic act forms vary tremendously. Pinching, biting, beating, flogging, injuring are all its forms. All this ill-treatment gives the sadist sexual satisfaction. Without these, the sex urge of the person is not excited.

24.8 VOYEURISM

A person suffering from voyeurism gets sexual pleasure when he observes the sexual organs of other persons or sex act being performed by others. Some of these perverts are so overcome by the desire to see the act that they trespass into premises of others and thus make them liable for legal action. If they can watch the act from their own residence, no action can be taken against them.

> *In colonial days one bachelor British Deputy Commissioner was so much fascinated by the sexual act of horses that he had given instruction to the veterinary hospital staff to call him when a mare in heat was brought to the hospital for mating. He would observe the mating process. (CH)*

24.9 FROTTAGE

In frottage sexual perversion, the pervert derives pleasure in rubbing against certain anatomical parts of females. Usually, he does so in crowded places like while travelling in buses, trains, or in cinema halls. Often he gets away with the perversion. He is sometimes caught and is taught a lesson for the misdemeanour.

24.10 MASOCHISM

Masochism is a sexual aberration in which the aberrant wants to be physically maltreated by his sexual partner, beating, biting, crushing, pinching painfully, are some of the physical tortures, which the masochist enjoys for sexual satisfaction. Some need even severer treatment. Others may derive sexual satisfaction from the maltreatment alone.

24.11 TRANSVESTISM

In transvestism, the person simulates other sex in dress, mannerism, and behaviour. Transvestism is quite common in India. The Hijrahs (eunuch) who practice as male prostitutes wear the female dress. They simulate female physical features such as wearing long hairs, putting on artificial breast balls. They use cosmetics to appear as females.

There is no law against the same in India.

Female Transvestism is becoming popular. Modern girls tend to keep short hairs and wear n shirt and trousers.

24.12 FETISHISM

Fetishism is a sexual aberration in which the aberrant derives sexual pleasure from a female's article of wearing apparel, ornament or even from shoes. The aberration is inoffensive most of the time, but sometimes the person starts stealing these articles. He thus becomes a criminal.

24.14 CASE LAW

24.14.1 Nirbhaya Rape-murder[2]

Author's Summary

It is a landmark judgment where the judges have utilised Forensic Science extensively for the dissemination of justice in this case of inhuman brutal rape- murder case.

The facts of the case are that the victim Nirbhaya, along with her friend (PW- 1) boarded a bus going to Dwarka/Palam. They noticed that six persons were already inside the bus. The accused did not allow anyone else to board. The bus moved and they put off the lights. A few minutes later, three persons (identified as accused Ram Singh, Akshay and a juvenile) started to abuse. Pw-1 objected that led to altercation. The two other joined the melee. PW-1 was beaten badly. He became immobile. Nirbhaya was raped by all the six and mauled so beastly/brutally that she died a few days later, in spite of the best medical help.

The police did an excellent job of locating and using all the available scientific evidence (CCTV footage for the identification of bus, fingerprints, bite marks, hair, DNA to inter-link the victims and the culprits) and presented an airtight case.

All the courts (trial, high court and the Supreme Court) appreciated the evidence. They found it **'rarest of the rare cases'** and sentenced them to death, excluding the juvenile.

Highlights italicised

The prosecution case, as projected, is that on 16 December 2012, the deceased, 'Nirbhaya' (not her real name), had gone with her friend, the informant, PW- 1, to the PVR situated in Select City Walk Mall, Saket to watch a movie. After the show was over, about 8:30 p.m., they took an auto and reached Munirka bus stand wherefrom they boarded a white coloured chartered bus [DL- 1P-C-0149, Ext.P1] which was bound to Dwarka/Palam Road, as a boy in the bus was calling for commuters for the said destination. As per the version of the informant, PW-1, the friend of the prosecutrix, the bus had yellow and green lines/stripes and the word "Yadav" was written on it.

After both of them had entered the bus, they noticed that six persons were already inside the bus, four in the cabin of the driver and two behind the driver's cabin. The deceased and the informant sat on the left side in the row of two-seaters and paid the fare of twenty rupees as demanded. Before they could get the feeling of a safe journey (though not a time-consuming

2. *Mukesh v State for NCT Delhi*, Criminal Appeal Nos, 607–08 of 2017, SC, decided on 5 May 2017. Bench: Dipak Misra, R Banumathi, and Ashok Bhushan.
The Supreme Court has discussed the evidence relating to DNA, Bite Marks, and Fingerprint lucidly, with numerous case citations.

journey), a feeling of lonely suffocation and a sense of danger barged in, for the accused persons did not allow anyone else to board and the bus moved and the lights inside the bus were put off. With the lights being put off, the darkness and the fear of the unexpected darkness ruled.

A few minutes later, three persons (who have been identified as accused Ram Singh, Akshay and a young boy, who has been treated as a juvenile in conflict with law) came out of the driver's cabin and started to abuse PW- 1. The young companion of the deceased raised opposition to the abuse that led to an altercation which invited the other two who were sitting outside the driver's cabin to join.

The spirit to oppose and the duty to save the prosecutrix had to die down and perilously succumb to the assault by the accused persons with the iron rods that caused injuries to his head, both the legs and other parts of the body and the consequence was that he fell on the floor of the bus to hear the painful cries of the lady who, he knew, was being treated as an object, an article for experimentation and prey to the pervert proclivity of the six but could do nothing except to hear unbearable cries made in agony and pain. His spirit was dead, and bound to.

As the prosecution story further unfurls, the two accused persons, namely, Pawan and Vinay, pinned the young man down and robbed the victims of their mobiles besides robbing the informant of his purse carrying a Citi Bank credit card, ICICI Bank Debit Card, his identity card issued by his employer-company, metro card, a sum of rupees one thousand, his Titan Watch, a golden ring studded with jewels and a silver ring studded with pearl, black colour Hush Puppies shoes, black colour Numero Uno jeans, a grey colour pullover and a brown colour blazer. As per the version of the prosecution, PW-1 was carrying two mobiles and the prosecutrix was carrying only one, and the accused snatched away all the three mobiles.

The overpowering was not meant to satisfy the avarice. As the accusations proceed, after the informant was overpowered, as it could only have a singular result, the accused persons, namely, Ram Singh, Akshay and the Juvenile in Conflict with Law (JCL) took the prosecutrix to the rear side of the bus and she was raped by them, one after the other.

After committing rape, the accused Ram Singh (since deceased), accused Akshay and the JCL came towards the informant, PW-1, and nailed him down; then the accused Vinay and accused Pawan went to the rear side of the bus and committed rape on the prosecutrix, one by one. PW-1 noticed that earlier the bus was moving at fast speed but after sometime, he felt that the speed of the bus was reduced and he saw that the accused Mukesh, who was driving the bus, came near him and hit him with the rod and he also went to the rear side of the bus and raped the prosecutrix.

The prosecutrix was brutally gang raped by the accused one after the other and she was also subjected to unnatural sex. Her private parts and her internal organs were seriously injured by inserting iron rod and hand in the rectal and vaginal region. As per PW-1, he had heard the cries of the prosecutrix like "chod do, bachao". PW-1 could hear the prosecutrix shouting in a loud oscillating voice. The prosecutrix was carrying a grey colour purse having an Axis Bank ATM card and other belongings.

The accused persons robbed her of her belongings and stripped her. They also took away the clothes of the informant while beating him with iron rods. The accused were exhorting that both the victims be not left alive. The accused then tried to throw both the informant and the prosecutrix out of the moving bus from its rear door but could not open it and so, they brought them to the front door and threw them out of the moving bus at National Highway No. 8, Hotel Delhi 37, Mahipalpur flyover by the side of the road.

227. After establishing the identities of each of the accused persons, the informant and the prosecutrix through DNA analysis, ***the DNA profiles*** *generated from the remaining samples, where*

the identity of biological material found thereon needed to be ascertained, were matched with the DNA profiles of the prosecutrix, the informant and the accused, generated earlier from known samples. Such an analysis cogently linked each of the accused with the victims as also with the crime scene. A summary of the findings in the report submitted by PW-45, Dr. B.K. Mohapatra, is as under:

"S.No.	*Accused*	*DNA Evidence*
1	*Ram Singh*	*Rectal swab from the prosecutrix contained DNA of male origin, which was found consistent with the DNA developed from the blood sample of this accused.*
		DNA profile developed from the blood stains from the underwear, T-shirt and slippers of this accused was found consistent with the DNA of the prosecutrix.
2	*Mukesh*	*DNA profile developed from the blood stains from the pants, T-shirt and jacket of this accused was found consistent with the DNA of the prosecutrix.*
3	*Akshay*	*Breast swab of the prosecutrix contained DNA of male origin which was found consistent with the DNA of this accused.*
		DNA profile developed from the blood stains from the jeans of this accused was found consistent with the DNA of the prosecutrix.
4	*Vinay*	*DNA profile developed from the blood stains from the underwear, jacket and slippers of this accused was found consistent with the DNA of the prosecutrix.*
5	*Pawan*	*DNA profile developed from the blood stains from the sweater and shoes and slippers of this accused was found consistent with the DNA of the prosecutrix."*

"Serial No.	*Identity of the victim*	*Findings of DNA Analysis*
	Informant	*The DNA profile developed from burnt clothes pieces was found to be of male origin and was consistent with the DNA profile of complainant.*
		The bunch of DNA profile developed from hair and blood stained pieces of paper recovered from the bus was found consistent with the DNA profile of complainant.
		The DNA profile developed from blood stained dried leaves collected from the place where both the victims were thrown matched with the DNA profile of complainant.
	Prosecutrix	*The DNA profile developed from blood stains from both the iron rods recovered at the instance of accused Ram Singh from bus was of female origin and was consistent with the DNA profile of prosecutrix.*
		The DNA profile developed from blood stains from curtains of the bus matched with the DNA profile of prosecutrix.
		The DNA profile developed from blood stains from seat covers was found consistent with the DNA profile of prosecutrix.
		DNA profile developed from blood stains from the bunch of the hair recovered from floor of the bus below sixth row seat, blood stains prepared from the roof of the bus near back gate, blood stains prepared from the floor of the bus near back gate, blood stains taken from side of back stairs of the bus, and blood stains taken from the inner side of the back door of the bus was found consistent with the DNA profile of prosecutrix.

228. Further, a summary of the DNA analysis of the biological samples lifted from the material objects such as the bus, the iron rods, and the ash and unburnt pieces of clothes is also worth producing here.

24.14.2 Judicial Activism in a Rape case[3]

Author's Summary

It is a case of rape and abduction. The IO failed to do his duty, which is highlighted through italicizing the relevant text s enunciated by the High court and endorsed by the SC. It is fortunate that the activism of the courts saw through the dereliction of duty and convicted the culprit u/s 376 IPC for rape and provided justice to the victim and passed strictures against the errant IO.

Highlights italicised

Relevant Extracts (Verbatim)

29. We now say something about PW-15, S.I. Bagal, who refused, to register an offence and on whom both the trial court and the High Court have commented, and in our view correctly. The trial court in paragraph 34 of the judgment observed as under:

> *It is a pathetic situation, when the citizen is confronted with the dishonest police officer. I am constrained to observe that the investigation done by S.I. Bagal P.W. 15, is not only suspicious but also dishonest and out and out in favour of the accused. I am making this observation with responsibility, I have scrutinized carefully the 3 statements recorded by S.I. Bagal, they are very cryptic and favourable to the accused. He did not care to ascertain the correct age of the victim girl, in a kidnapping and rape case. He did not register an offence against the accused. I fail to understand as to what interrogation of the accused he has done. He has obtained the signature on the statement of PW-4 Pushpa and Eknath and right hand thumb impression on the statement of Smt. Vimal for what reason, I do not understand, on three statements. At least he could have registered the offence for kidnapping after taking extract of birth from the school. If he wanted to ascertain the correct date from her father Pandurang and he was aware that PW-1 Pandurang was in K.E.M. Hospital and he wanted to obtain Hospital record, but he never cared to visit K.E.M. Hospital and to record the statement of Pandurang. He was trying to shift the burden on the Senior P.I. Sharma. Merely, he had produced these three statements in a routine manner before P.I. Sharma, on the next day. There is no guarantee that he had faithfully recorded statements of all these three witnesses. The reading of the three statements clearly indicates that those are completely in favour of the accused. The entire conduct of S.I. Bagal in the investigation has a smell of suspicion and dishonesty.*
>
> *The High Court also observed about the conduct of PW-15, S.I. Bagal as under:*
>
> *In the present case, the investigation conducted by S.I. Bagal was completely defective and casual. He has not even registered the offence. The learned trial Judge has observed that the attitude of S.I. Bagal was completely dishonest and partial to the accused. On closer scrutiny of the record, we are inclined to agree with the observations of the learned Judge. We have reason to believe that S.I. Bagal deliberately refused to register the offence in order to help the accused at the costs of the prosecutrix. But despite this deficiency, the prosecution has successfully provided the offence of rape. We have, therefore, no hesitation in confirming the conviction recorded by the trial court under section 376 of the IPC.*

30. In the facts and circumstances of this case, the comments made by the trial court and the High Court about the manner in which S.I. Bagal conducted the first investigation are well justified.

3. *Vishnu v State of Maharashtra*, AIR 2006 SC 508 : 2005 AIR SCW 6149 : 2006 Cr LJ 303 (SC).

24.14.3 Age of the Rape Victim[4]

Author's Summary

It is a case of rape where the culprit took the plea that it was a case of consent and the victim was of the age of consent. He hired a radiologist who supported his Claim. However, the SC accepted the birth entry in the register and the school record and convicted the culprit.

Highlights italicised

2. The factual matrix may be noted briefly:

The prosecutrix – Kumari Pushpa at the relevant time was residing with her parents Pandurang – PW-1 and Vimal – PW-13 at Khar Danda, Mumbai. The accused was known to the prosecutrix as they were residing in the same locality. The accused was also a friend of the maternal uncle of the prosecutrix. She used to visit her maternal uncle's house where she used to meet the accused. Pandurang, father of the prosecutrix was admitted at K.E.M. Hospital for treatment of his eyes. The prosecutrix used to take food and tea to the hospital for her father.

3. On 10th July, 1980 the prosecutrix had gone to the hospital at about 11.00 a.m. carrying food and tea for her father. She left the hospital at about 3.30 p.m. While she was coming out of the gate of the K.E.M. Hospital, the accused who was a taxi driver met her at the gate and inquired as to where she was going. The prosecutrix told the accused that she was on her way to her residence. The accused told her that he had his own taxi and he would drop her at her residence at Danda. Upon such offer, the prosecutrix got into the taxi. When the taxi came to the Linking Road Junction, the accused told her that his wife was admitted in Nanawati Hospital and he would go and see his wife in the hospital and thereafter he would drop her at her residence.

The accused then took the taxi to a small hotel representing that it was Nanawati Hospital. The accused took her inside the room of the hotel, bolted the room from inside and committed rape on her by threatening that in case of her shouting, she would be finished. Both of them came out of the hotel room and the accused dropped her home at 5.45 p.m. in his own taxi.

4. *The prosecutrix reached home bleeding profusely from her private parts. After half an hour, she became unconscious. Her mother Vimal PW-13 and her brother Eknath took her in a taxi to Bhabha Hospital. She was examined by Dr. Dilip Chaniary-PW-12 of Bhabha Hospital. After she regained consciousness at about 10.00 p.m. she narrated the incident to her mother that she was raped at about 5 p.m. and told that she was bleeding from her vagina since 5.30 p.m.*

5. PW-15, S.I. Bagal, who was attached to Bandra Police Station was intimated about the incident on telephone, PW-15, along with a Police Constable, reached Bhabha Hospital for inquiry. He contacted the prosecutrix in the ward. He also questioned her about the incident and recorded her statement. He also recorded the statements of her mother Vimal and brother Eknath. He further made inquiry about the age of the girl from the brother and mother of the prosecutrix. Thereafter, he went to the school where she studied last and collected the school leaving certificate from Khar Upper Municipal School on 11th July, 1980. PW-15 did not register any case presumably thinking that the age recorded in the school leaving certificate was more than 16 years and she was a consenting party to sex. He was of the view that there was not enough material to register a case. He also stated that he called the accused for further inquiry on 3-4 occasions but did not think it necessary to register the offence or to carry further investigations. The conduct of PW-15, S.I. Bagal has been commented upon and deprecated by both the trial Court and the High Court, which we may refer at an appropriate stage, if need be.

8. During the course of investigation, S.I. Parab recorded the statements of the witnesses including the prosecutrix and her parents and collected relevant documents. It is revealed from the documents collected by him that Pushpa's (prosecutrix) date of birth was 29th

4. *Vishnu v State of Maharashtra*, AIR 2006 SC 508 : 2005 AIR SCW 6149 (SC) : 2006 Cr LJ 303.

November, 1964 and she was below 16 years of age at the time of commission of offence on 10-7-1980. The accused was arrested on 3rd November, 1980 and during interrogation, the accused took them to the Marwadi Hotel at Juhu where the prosecutrix was taken by him. The panchnama was drawn *vide* Exh. 7. After close of the investigation, a *prima facie* case was established and a charge-sheet against the accused under sections 366/376, IPC and section 57 of the Bombay Children Act was filed before the Additional Chief Metropolitan Magistrate, 9th Court, Bandra, Bombay. Thereafter, the case was committed to Sessions. Before the Sessions Court, the prosecution examined as many as 14 witnesses and led documentary evidence with regard to the establishment of the age of the prosecutrix and after the conclusion of the trial, the accused was convicted and sentenced as stated above.

9. We have heard Mr. U.U. Lalit. learned Senior Counsel for the appellant and Mr. Sushil Karanjkar, learned counsel for the respondent at length.

10. Before us the learned Senior Counsel for the appellant strenuously urged that there are two dates of birth of the prosecutrix, one – 29-11-1964 (recorded in the Date of Birth register of the Bombay Greater Municipal Corporation and register of Kashibai Hospital, Santa Cruz, Bombay, where Pushpa was born): and second – 29-6-1963 (the date of birth recorded in the school leaving certificate of Khar Upper Municipal School) which have created a doubt and are capable of two opinions — One in favour of the accused and the other against the accused; the one in favour of the accused should be accepted and the accused be acquitted by giving him the benefit of doubt. He further contended that since the sexual intercourse is consensual, therefore, unless it is established that the prosecutrix is below the age of 16 years, the accused is not liable to be punished in view of the definition of 'rape' under section 375 of IPC namely, clause sixthly. This submission deserves outright rejection.

11. The question whether the date of birth of the prosecutirx is 29th November, 1964 or 29th June, 1963 is no more in controversy.

12. The date of birth of the prosecutrix, as of 29-11-1964, has been recorded concurrently by both the trial court and the High Court on consideration of the evidence of PW-1, Pandurang, father of the prosecutrix and PW-13, Vimal, mother of the prosecutrix, corroborated by the age of the prosecutrix recorded in the date of birth register of Greater Bombay Municipal Corporation and the register of Kashibai Hospital, Santa Cruz, where the prosecutrix was born. The evidence of PW-1 and PW-13, father and mother of the prosecutrix supported by contemporaneous documents/registers produced by the prosecution like date of birth register in Bombay Municipal and the date of birth register in the Hospital where the prosecutrix was born and the evidence of the doctor clearly establish that the prosecutrix was born on 29-11-1964. Therefore, this question need not detain us any longer in view of the observations of this Court in the case of *Bharwada Bhoginbhai Hirjibhai v State of Gujarat*, AIR 1983 SC 753 : 1983 Cr LJ 1096 : 1983 3 SCC 217, this Court held at para 5 page SC 755:

> A concurrent finding of fact cannot be reopened in an appeal by special leave unless it is established: (1) that the finding is based on no evidence, or (2) that the finding is perverse, it being such as no reasonable person could have arrived at even if the evidence was taken at its face value, or (3) the finding is based and built on inadmissible evidence, which evidence, if excluded from vision, would negate the prosecution case or substantially discredit or impair it, or (4) some vital piece of evidence which would tilt the balance in favour of the convict has been overlooked disregarded or wrongly discarded.

13. The present is not a case of such a nature which would warrant our interference. That apart, what was recorded by the High Court is worthy to be noted. In paragraph 13, the High Court has noted as under:

> *At the outset, it is required to be noted that the finding recorded by the trial court that Pushpa was less than 16 years of age on the date of the commission of the offence is not at all challenged by Mr. Samant.*

Noticing the aforesaid observation of the High Court, this Court while issuing notice on 19-7-1999, noted as under:

> *Learned counsel for the petitioner contends that even though the counsel for the petitioner in the High Court did not challenge the age shown in the birth register, there are materials*

for indicating that the said date cannot be accepted as a correct one. He invited our attention to the date of birth shown in the School Leaving Certificate. According to the counsel if that is to be given credence the prosecutrix would be far above the age of 16 years on the date of occurrence. Question of consent will very much depend upon the exact date of birth of the prosecutrix. In the light of this we feel it necessary to examine the record.

14. It is because of that observation we allowed the learned counsel for the appellant to make submissions on the question of date of birth.

15. We have also perused the entire records.

16. The school certificate which has been relied upon by the accused is marked Exh. 37, the translated copy of which reads:

"Khar-Danda Higher Secondary Marathi School

Birth date of ex-student of said school – Pushpa Pandurang Satrange as per school register is twenty-ninth June, Nineteen Sixty Three – 29-6-1963.

Submitted dt 11-7-1980.

Sd/-

For Principal

Khar Danda Higher Secondary Marathi School.

17. *On a bare perusal of the certificate, it is noticed that it is not an authenticated copy and no one has been examined to prove the age of the prosecutrix recorded in the school certificate.*

18. *PW-1, Pandurang is the father of the prosecutrix. He has stated that his daughter Pushpa (prosecutrix) was born on 29-11-1964. He has also stated that Pushpa was born at Kashibai Hospital Santa Cruz, Bombay. This witness was subjected to lengthy cross-examination but his statement that the prosecutrix was born on 29-11-1964 remained unimpeached. In fact, in the cross-examination, this witness clarified that the date of birth given in the school was incorrect and he further clarified that the correct date of birth of Pushpa is 29-11-1964. It is a common knowledge that very often parents furnish incorrect date of birth to the school authorities to make up the age in order to secure admission for their children. Therefore, we do not see any infirmity in the statement of the witness, who is the father of the prosecutrix, stating that the prosecutrix was born on 29-11-1964.*

19. ***PW-13, Vimal is the mother of the prosecutrix. She has also stated that her daughter, Pushpa (prosecutrix) was born in Kashibai Hospital, Santa Cruz, Bombay on 29-11-1964. To prove this, the prosecution has examined Dr. Shashikant Awasare, who is one of the proprietors of Dr. Kashibai Nursing Home, Santa Cruz (West), Mumbai. He has produced the registers for the year 1964. He has also produced the entry at Sr. No. 293, Exh. 18. The entry shows that Vimal – PW-13 gave birth to a female child on 29th November, 1964. The prosecution has also produced a Certificate of Birth Registry of Municipal Corporation of Greater Bombay which shows the registration of a female child of Pandurang – PW-1 and Vimal – PW-13 and the date of birth is shown as 29-11-1964. To prove this the prosecution has produced on record the Birth Register Book No. 24 of Municipal Corporation of Greater Bombay showing entries from 4th November, 1964 to 5th February, 1965. The entry at Sr. No. 542, dated 16th January, 1965 is in respect of the birth of the female child to Vimal and the birth date is shown as 29th November, 1964. These two unimpeachable documents clearly corroborate the statements of PW-1 and PW-13 in all material particulars that the prosecutrix was born on 29th November, 1964. Men may lie but the documents do not. These two unimpeachable documents clearly establish the fact that PW-4, Pushpa was born on 29th November, 1964. Therefore, she was below 16 years of age on 10-7-1980 and her consent, if any, is immaterial under clause Sixthly of the definition of "rape" under section 375, IPC.***

20. Mr. Lalit referred us to the evidence of Dr. Bhimrao – PW-10. Dr. Bhimrao was the Medical Officer, Police Hospital, Nagpada, before whom the prosecutrix was produced on 3-11-1980 for medical examination. According to him, she had fourteen teeth (7/7) in upper jaw and thirteen teeth in lower jaw. The doctor opined, among others, that her

hymen showed old healed tears at 3-9 O'clock position. For the determination of the age of the prosecutrix, PW-10. Dr. Bhimrao has stated as under:

> *I X-rayed for ossification test. I took her X-rays of wrist, elbows and shoulder joint. Elbow joint is united which unite at the age of 13/14 years. The wrist joint is united which unites at the age of 16/17 years. The shoulder joint is united which unites at the age of 18 years. From physical findings and ossification test and secondary sex characteristics I am of the opinion that the age of the girl Pushpa was 18-19 years with error of margin 6 months on either side. From the finding of internal examination of external genitals I am of the opinion that the said girl was subjected to sexual intercourse. Notes of examination prepared by me. It bears my signature and also of Dr. Gawane.*

21. It is urged before us by Mr. Lalit that the determination of the age of the prosecutrix by conducting ossification test is scientifically proved and, therefore, the opinion of the doctor that the girl was of 18-19 years of age should be accepted. We are unable to accept this contention for the reasons that the expert medical evidence is not binding on the ocular evidence. The opinion of the Medical Officer is to assist the Court as he is not a witness of fact and the evidence given by the Medical Officer is really of an advisory character and not binding on the witness of fact.

22. In the case of *Madan Gopal Kakkad v Naval Dubey,* (1992) 2 SCR 921 : (1992) 3 SCC 204 : 1992 AIR SCW 1480 (1494) this Court has considered a similar question and pointed out in paragraph 34 at page SCC 221 as under:

> 34. *A medical witness called in as an expert to assist the Court is not a witness of fact and the evidence given by the Medical Officer is really of an advisory character given on the basis of symptoms found on examination. The expert witness is expected to put before the Court all materials inclusive of the data which induced him to come to the conclusion and enlighten the Court on the technical aspect of the case by explaining the terms of science so that the Court although, not an expert may form its own judgment on those materials after giving due regard to the expert's opinion because once the expert's opinion is accepted, it is not the opinion of the Medical Officer but of the Court.*

23. We are of the opinion that this contention of the counsel for the appellant will be of no assistance in the face of evidence of fact from the mouth of PW-1 father and PW-13 mother, well corroborated by the register of the date of birth of Bombay Greater Municipal Corporation and the evidence of Dr. Shashikant Awasare, who is one of the proprietors of Dr. Kashibai Nursing Home, Santa Cruz (West), Mumbai, produced by him which shows that PW-4 Pushpa was born on 29-11-1964.

24. In the case of determination of date of birth of the child, the best evidence is of the father and the mother. In the present case, the father and the mother-PW-1 and PW-13 categorically stated that PW-4 the prosecutrix was born on 29-11-1964, which is supported by the unimpeachable documents, as referred to above in all material particulars. These are the statements of facts. If the statements of facts are pitted against the so-called expert opinion of the doctor with regard to the determination of age based on ossification test scientifically conducted, the evidence of facts of the former will prevail over the expert opinion based on the basis of ossification test. Even as per the doctor's opinion in the ossification test for determination of age, the age varies. In the present case, therefore, the ossification test cannot form the basis for determination of the age of the prosecutrix on the face of witness of facts tendered by PW-1 and PW-13, supported by unimpeachable documents. Normally, the age recorded in the school certificate is considered to be the correct determination of age provided the parents furnish the correct age of the ward at the time of admission and it is authenticated. In the present case, as already noted, the parents had admitted to have given an incorrect date of birth of their daughter, presumably with a view to make up the age to secure admission in the school. Apart from this, as noticed earlier, the school certificate collected by PW-15 S. I. Bagal was not an authenticated document. Nobody was produced to prove the date of birth recorded in the school certificate. The date of birth recorded in the school certificate as 29-6-1963 is, therefore, belied by the unimpeachable evidence of PWs-1 & 13 and contemporaneous documents like date of birth register of Greater Bombay Municipal Corporation and the register of the Nursing Home where the prosecutrix was born and proved by Dr. Shashikant Awasare, as noted above.

25.1 IMPORTANCE

Computers are being used extensively not only in science and industry but also in household work and for entertainment. Today one cannot even think of education, communications, space research, defence weaponry, travel and transport, publishing industry without computers. In short, computers have become indispensable in all our lifestyles.

25.1.1 Police Work

Computers have helped the police department in a big way to improve its functioning on all grounds. They are used extensively in all aspects of their functioning. The major applications are:

- *Modus Operandi* records
- Fingerprint records
- Weapon possession records
- Vehicle registration records
- Traffic Control
- Lost or stolen vehicles records
- Absconders' records
- Missing Persons' records
- National and International Communications including e-mail, Internet and Fax facilities
- Equipment and Resources Information
- Manpower Availability and Deployment
- Service records of the personnel of the force
- Crime Cases records
- Court Cases records
- Record of Suspects
- Record of Drug Users, Peddlers
- Digital Photography
- Image Enhancement
- Police Interrogations
- Movement of the criminals through the call record in their mobile phones
- Recent contacts of the criminal with other criminals from cell phones
- Frequency of contacts with various individuals
- Miscellaneous information contained in computers and mobile phones.

Computers are also being used extensively by the police assisting organisations and other wings of the criminal justice system for many reasons, including the Photofit reconstruction of facial features, psycho-linguistic analysis, and brain printing.

25.1.2 Forensic Science

In Forensic Science Institutions, computers are being used in all aspects of their work. In addition to the usual office work, including manpower management, they are being used in the following:

25.1.2.1 Crime scene

Digital Photography is used to record the crime scenes now. The computers store these digital photographs. Computers are also used to store other photographic data (mug photographs). The computers provide a convenient mode to circulate photographs and other data to concerned organisations or units, or their printouts can be prepared and circulated.

Currently, computers are being used to prepare 3D sketches of the crime scene using special software.

25.1.2.2 Fingerprints

Searches and comparisons of fingerprints are no longer manual. Computers are carrying out the work with high efficiency. They are also processing and enhancing the readability of faded fingerprints. National Crime Record Bureau (NCRB), Ministry of Home Affairs, Government of India, has developed a system termed as FACTS — an acronym for Fingerprints Analysis and Criminal Tracing System. The system uses a scanner to convert the fingerprint or its image into digital data, which is stored in a computer. When a new crime fingerprint is to be identified, it is digitized (converted into digital data) and fed into the computer. On demand, the computer carries out the comparison of the data with similar data in the computer. If the computer hits a match, it reveals the details of the person from whom it has come. The whole work is done at high speed.

25.1.2.3 Tracks and Trails

Computer technology has proved a boon for processing track marks evidence:

- Processing of holograms
- Enhancement of indistinct images
- Comparison of track evidence
- Evaluating gait patterns in CCTV footage to identify the target person

25.1.2.4 Forensic Ballistics

Ballistics has adopted computer technology in its functioning mainly for the following evaluations:

- Data relating to Ballistics tables have also been computerised. The factors like air resistance, structural, and compositional features, which introduce variations are better managed with computerised computations.
- Automatic comparison of firearm marks (Striations and static marks) on the fired ammunition is being done through instrument controlled by computers.

  USA is using a system called NIBIN (National Integrated Ballistics Information Network) which, like fingerprint automation, keep records of the firearm marks. The system compares the marks on new fired crime projectiles and cartridge cases with the corresponding stored data and identifies the weapon used. The system has great utility where the same weapon is used in many crimes. The system has distinct advantage where the comparisons of bullets and cartridge cases are carried out at

different and distant places. The images are transferred *via* internet has made it possible to do so. There are other automatic comparison systems also.

- Data on firearms, ammunition, and pellets' spread of various shotguns at various ranges are maintained routinely by most of the laboratories in the computers for day-to-day consultations.

25.1.2.5 Disputed Documents

The computers are becoming indispensable in the evaluation of disputed documents:

- The comparison of signatures is being done *via* digitalized images of signatures. This technique can reduce bank frauds considerably.
- Typescript examination has been facilitated considerably by computers. They help to find out additions, alterations, and obliterations by evaluating the spacing patterns, linear and vertical alignment variations and defects.
- Faded and mutilated writings are better evaluated by image enhancement technology.
- Enlarged prints of very high quality permit better evaluations and comparisons of the handwritings, signatures, initials, additions and other alterations.
- Comparison of seals, stamps, logos, insignias is facilitated by computers in conjunction with scanners
- Presentation of evidence of handwriting and signatures has been improved tremendously. Segmentation, enlargements, and increasing contrast/brightness have improved the presentation.

In a recent case, the signature of the victim were partly on a bank loan form and partly on a stamps paper stuck on the form, the signature part on the stamp paper was barely visible. The victim did admit that he had signed the form but not the stamp paper the deputed signature was put under a scanner and the colour of the signature was gradually reduced. At one stage the true picture of the portion of the signature on stamp paper could be obtained. It was found that un-extrapolated signature part on the stamp paper was forged. (CH)

25.1.2.6 Chemical Analysis

Practically all instrument used in the analysis is computer controlled. The computer controlled instruments are now doing the interpretation of instrumental analyses of poisons/drugs and other chemicals increasingly. They contain the software, which carries the library of the analytical data of the standard sample materials analysed by the instruments. Software, thus, on command, compares this data with the data generated from the clue material automatically and the result is displayed on the monitor. The instruments also provide printouts of the findings in the form of graphic traces and data.

The instruments and technique contain inbuilt computer evaluations and interpretation system. The following are, however, the ones, which have made the work of the Forensic analysis easy, reliable and efficient. They not only reveal the identity but the quantity also.

1. Atomic Absorption Spectrophotometer
2. Neutron Activation Analysis
3. Spectrographs
4. Microprobe
5. Scanning Electron Microscope, with E.D.X. system
6. GLC, HPLC, TLC, HPTLC
7. GS-MS,

8. UV, IR, NIR, FTIR, Spectrophotometers
9. Microscopes-Quantimat
10. Comparison Microscope

The computerised instruments are being utilised for evaluations of all sorts of clue materials including:

1. Poisons
2. **Narcotics** and psychotropic substances
3. **Glass;** Data Bank on their properties like Refractive Indices, and Densities are available.
4. **Paints;** they are being evaluated for 16 parameters through computer software specially created for the purpose.
5. **Microtraces;** dust, dirt, soil, plant residues, animal residues.
6. **Liquors;** for composition, adulteration, identification, quantitation of the components.
7. **Drunkenness;** it is an increasing menace. Computerised instruments like computerised breath analysers indicate the extent of drunkenness among drunken drivers and provide printouts at the spot itself.
8. **Computerised arson detectors;** confirm the arson nature of the fire at the spot itself.
9. Computerised GS-MS identify initiators, accelerants, promoters in arson cases.
10. **Explosive Detectors;** they are computerised instruments which detect explosives and explosion products through their vapours. Comparison of data from various explosion sites may inter-link the serial explosions.

25.1.2.7 Biological Analysis

Computers are being utilised in the evaluation of biological evidence of all types. They are efficient in processing and interpreting biological evidence. Computers have made themselves indispensable in the following evaluations:

1) DNA Profiling

DNA profiling is the biggest breakthrough in Forensic Science of all times in forensic identifications. It has come almost a hundred years after the discovery of fingerprints for personal identifications. Computers have helped to evaluate and compare the fragments of the DNA molecules. The comparison of the profile of a suspect with the profile of the evidentiary material may identify or eliminate the suspect as the criminal as no other evidence can do.

All body fluids and materials, skin, flesh; even bone or hair can be used to develop DNA profiles. Some countries, like the USA and UK, have organised a DNA database of all the convicts to identify recidivists.

2) Anthropological Evidence

A lot of data relating to bones and skeletal remains, including that on dentures, skulls has been gathered and stored in computers. The data is being utilised to identify and ascertain various aspects of the deceased to whom the remains could belong:

1) Age, sex, height and built of the subject
2) Cause of death
3) Time of death
4) Deformity, injury or any bone disease
5) Facial Reconstruction
6) Skull Superimposition

Due to the availability of extensive data the interpretation are quite accurate.

3) Facial Reconstruction

Facial reconstruction is an important aspect and aid in the identification of the deceased person from the skull. A lot of data has been generated about the thickness of skin and flesh at various sites of the face. The sculpturing material is plastered to various thicknesses in accordance with age and sex of the subject, on the skull itself or on its sturdy cast. With appropriate skin tint, eyes, and ears a life-like face is created.

Computers have, more or less, dispensed with the above reconstruction technique. The computer is fed with the skull structural data, and other facial feature data and cranial structure are created in three dimensions on the monitor with special software. The facial features in flesh-like shades are created and contoured according to depth and thickness data already available with the computer. The facial figure thus obtained is digitized, and the obtained data are compared with similar data generated with that of the suspected subject. The computerised reconstruction has not only speeded the process but it has increased the accuracy manifolds. It has also greater maneuverability.

4) Skull Superimposition

Skull superimposition on the photograph of a suspected subject, for identification purposes, have been in use for decades now — since the Ruxton case in which the technique helped to establish the identity of the victims for the first time in the forties of the last century. Computers have speeded up the process tremendously. They have improved the accuracy also, many times.

25.1.2.8 Medico-Legal Work

Doctors are not only utilising computers in the treatment of the patients but medico-legal experts are also using computers in solving complex medico-legal problems:

a. Subcutaneous Injuries

In medico-legal cases, it is usually difficult to evaluate internal injuries, especially when the injured is still alive. Computerised scanning devices evaluate the nature and extent of damage, to determine whether the injury is grievous or otherwise. In fatal cases, it helps to ascertain their contribution toward the cause of death.

b. Post-mortem Examination

In mass disasters, post-mortems are conducted mainly to identify the victims. The identification data of each individual is collected and serially stored in the computer. This data of the suspected deceased persons is collected from the available sources (relatives, acquaintances, family doctor). The data from the two sources are then compared to identify the mutilated deceased. The relevant data collected is:

- Dentures, broken, extracted or repaired teeth, and their alignment defects, which provide excellent evidence.
- Previous bone injuries and their X-rays and deformities
- Scars, tattoo marks, and birth marks, if available
- Anthropometric measurements for developing portrait Parle
- Description of wearing apparel

Similar descriptions and data are also kept in cases of unknown and unclaimed dead bodies. Computerised data is also fed into the computers and relayed over the network or internet. They have been identified and their relatives located frequently through this mode.

25.1.2.9 Medico-legal Research

In medico-legal work one of the trickiest problems, which has defied an accurate solution, is the finding of the time of death. This is because it involves many variables:

- Health of the subject
- Cause of death
- Environmental conditions like wind, temperature, humidity
- Existence of special circumstances like addiction
- Up-keep of the body (exposure to elements, buried under snow, water, sand, earth)

Computers are now being utilised to record and process the data of these variables. The extensive and accurate processing of the variables, it is hoped, would give more accurate results.

25.2 COMPUTERS AND LAW

Computers are being used increasingly by lawyers and judges, in their day-to-day work to store, classify and locate:

- Correct laws.
- Correct case law.
- Correct sources of scientific help.
- Precedence and conventions
- Law library in Internet, computers pen drives,

These huge libraries are now giving way to computers, pen drives, CDs and floppies. On the flick of the mouse or on pressing of a button the information on the required topic, whether it is on law or on expert evidence, is before the judge or the lawyer, whoever has requisitioned the same. Again, if it is so required, a printout of the information can be obtained.

Outstanding luminaries in law even go beyond. They record the summaries of the evidence on day-to-day basis. They anticipate and note the possible line of defence or of prosecution and collect appropriate material information to rebut the same. The simpler uses of computer are to:

- Keep inventory of the cases on day-to-day basis.
- Prepare brief on the case.
- Prepare a daily roaster.
- Study and collect case law *via* internet.
- Retrieve precedents of similar cases.

The lawyers and the judges are somewhat slow in picking up the technology but the advantages are so many and so impressive that no lawyer worth the fight or an enlightened judge can ignore the onslaught of the computers.

25.3 NATURE

The computer is a device to store, preserve, process, and to reproduce data on demand in the desired form. It is a complex instrument with still more complex components. It started with computing figures and digits. Now all types of data, digits, letters, pictures, graphics, voice, action can be preserved, processed and reproduced or created at unbelievable speeds, with uncanny accuracy. Its complexity involves high technology. Yet the instrument is so streamlined that with practice one can use the instrument usefully without knowing the technicalities involved. As this discussion is meant for non-technical potential users, the technical details have been omitted. The computer has essentially the following components:

1. Central Processing Unit (CPU).
2. Input, throughput and output devices.

25.3.1 CPU

Central processing unit is the main part of the computer. It contains the memory, storage of information and the system and application software. The nature, extent and capacity of the computer determine the configuration of the computer. Special software for specific purposes is also used. Microprocessors have drastically reduced the bulk of computers.

The CPU (also known as processor), of a computer, is its brain. It is a single chip and contains a control unit and the Arithmetic Logic Unit (ALU).

The processor is responsible for interpreting every code it receives from the other computer components and making it usable in the operating system. The processor's speed determines the overall speed of your computer.

25.3.2 Motherboard

The motherboard is that part of a computer that connects all of the other computer parts together. It is a printed circuit board and includes the CPU and memory. It includes expansion options for high-end graphic displays and additional devices. Motherboard specifications are designed around which CPU the computer uses.

25.3.3 Hard disk

The hard disk is also known as hard drive. It is the information storage device. It stores all sort of information in the computer; whether it is text, picture or other graphics. It has a large capacity, which is measured in MB/GB/TB.

The hard disk is a set of disk platters, which are located inside the computer. It is a fixed component and cannot be separated.

25.3.4 Random Access Memory (RAM)

RAM operates an instant memory to operate computers. It is always in use as a temporary location to carry out the instruction given to the computer. There are many types of RAMs, with varying speeds.

25.3.5 Input Devices

Input devices are a keyboard, a microphone (sound input), scanners (for graphic inputs) and network and Internet connection. The keyboard is the main input device. Downloading from the Internet is becoming an important input (as well as an output device). Likewise, scanner is an optional input device. But its utility is increasing every day.

25.3.6 Output Devices

Output devices vary. Most important and perhaps indispensable is the monitor. The printer is an optional but important device for output purposes.

Network and Internet modem connects the computer with the outside computer world, which is used both for input and output purposes. The network connects the computer *via* cables and microwave towers. It may be:

1. Local Area Network (LAN)
2. Wide Area Network (WAN)

   Some organisations use the two systems for internal connectivity, for secrecy and security of the information.
3. Internet

Internet to start with was connectivity among a group of computers. Now it is a global network of computers and provides worldwide connectivity. There are a number of organisations, which provide connectivity to other computers through their network. They use microwave towers or satellites for the inter-connection. The network of networks is the Internet.

Internet connectivity may be termed a technology. It has no tangible site. The intangible Internet activity site is called cyber space. The Internet has been compared to the spider web, but the Internet covers the whole world and known as World Wide Web (WWW). It connects any two computers, using the Internet, anywhere in the world. The connecting media does not involve physical entities in the usual sense.

25.4 COMPUTER WORK

Computers handle data of all sorts. They carry out a number of tasks relating to data:

1. Compute
2. Store
3. Arrange, rearrange
4. Compare
5. Transfer to other files
6. Print printouts (with printers)
7. Transmit or receive (FAX)
8. Provide E-mail facilities
9. Provide wealth of data information available on the Internet through Internet modem
10. Provide online business, education and entertainment facilities

The tasks are performed by computers with speed and accuracy, which make them indispensable in all organisations and even in homes.

CHAPTER 26

COMPUTER FORENSICS
(Computer/Cyber Crimes)

SYNOPSIS

26.1 General 1432
26.1.1 Definition 1432
26.1.2 Computer crimes 1433
26.1.3 Computer and crime 1433
26.1.4 Computer Crimes: Motives 1434
26.1.5 Cyber crimes 1435
26.1.6 Characteristics 1435
26.1.6.1 Intangible Evidence 1435
26.1.6.2 Substantial Losses 1435
26.1.6.3 Prevalent Climate 1436
26.1.7 Investigative Impediment 1437
26.1.7.1 Hi-tech Crime 1437
26.1.7.2 International Crime Global Ramification 1437
26.1.7.3 No-Scene Crime 1437
26.1.7.4 Faceless Crime 1437
26.1.7.5 All/No-time Crime 1437
26.1.7.6 Inadequate or non-existent laws on national or international level 1437
26.1.7.7 Inadequate international co-operation 1437
26.1.7.8 Inadequate governmental or public defence 1437
26.1.7.9 General lack of information about their modus operandi or handling 1437
26.2 Classification 1438
26.2.1 Internet Crimes 1438
26.2.2 Computer Frauds/Crimes 1439
26.2.2.1 Information Piracy and Vandalism 1439
26.2.2.2 Theft of Information Services 1439
26.2.2.3 Organised Crime 1439
26.2.2.4 Infringement of Copyrights 1440
26.2.2.5 Theft 1440
26.2.2.6 Wire Tapping 1440
26.2.2.7 Data Destruction 1440
26.2.2.8 Virus 1440
26.2.2.9 Logic Bombs 1440
26.2.2.10 Spy Software 1441
26.2.2.11 Money Laundering 1441
26.2.2.12 Electronic Funds Transfer 1441
26.2.2.13 Electronic Personation 1442
26.2.2.14 Hacking 1442
26.2.2.15 Crackers 1442
26.2.2.16 Software Piracy 1443
26.2.2.17 Miscellaneous 1443
26.3 Computer Criminals 1444

26.9.1 Computer Records Confession 1457

Fig. 26.1

Computer forensics is a branch of digital forensic science. It handles crime evidence legally found on the computer and related digital storage devices, including hard disk, files, and concerned software. The purpose of these investigations is to study and analyze the data forensically to find if there is any illegality in these digital files and contents. The findings are submitted/furnished in the form of a report.

Computer Forensics is synonymous with computer crime, cyber crimes, e-crimes, net crime, and electronic crime.

26.1 GENERAL

The advent of computers has completely revolutionised the functioning of science and technology institutions, the working of the offices, including that of the courts and homes. The unthinkable speed, un-imaginable accuracy, and elimination of drudgery of work and cost-effectiveness have made the computers and like devices indispensable to all concerned. They have made possible certain scientific developments; for example, space travel, Ballistic missiles, which were unthinkable otherwise. However, it is not a one-sided blessing. The computers have also facilitated crime in a big way: number wise, volume-wise and, particularly, losses-wise. Thus, they have created a big headache to the public in general and the law-keepers in particular. The criminal has not been slow to exploit the potential of the computers.

Computer crimes are known by many different names, including cybercrime, net crime, e-crime, or electronic crime. They all involve computers and networks in most of the crimes. The computer crimes include identity thefts, hacking, spams, and financial frauds. The criminal is also using computer and Internet in most of the traditional crimes, such as theft, blackmail, pornography, forgery, embezzlements, fraud, and money laundering, which today are also conducted on the Internet on much vaster scales.

26.1.1 Definition

Computer crimes are illegal activities involving computer systems. It is an act using computers, the Internet, Internet devices, and Internet services to defraud people, companies, or government agencies for money, revenue, or Internet access. Computer crime criminals are well-versed in computer technology and use them in their nefarious activities. He illegally browses, or steals/

corrupt/destroy the person's (or group of persons') data. Often the act corrupts the computer or the data files.

26.1.2 Computer crimes

There are numerous types of computer crimes; and the number and variety in increasing with the passage of time. The important illegal computer activities include:

1. **Child pornography;** making or distributing child pornography.
2. **Cyber bully and Cyber stalkers;** stalkers and bullies follow a person on line and harass him/her.
3. **Cyber terrorism;** threatening, hacking, and blackmailing messages.
4. **Denial of Service;** some criminals overload computer system to make it useless for normal functioning.
5. **Espionage;** spies spy on a person's/organisations/installations/business houses.
6. **Identity theft;** Identity thieves misuse the credit card/his name/fame for personal gains.
7. **Inducting** Malware (viruses and spyware); to make the computer non-functional.
8 **Intellectual property theft;** stealing intellectual/scientific discovery data and using it to make money/name /fame.
9. **Phishing;** It is stealing personal data of a person, for misuse.
10. **Salami;** it is slicing money in small amounts, from each of many online transactions through command to the computer.
11. **Scams;** they are frauds to swindle people/organisations/governments.
12. **Spamming;** sending unsolicited e-mail to numerous persons to waste their computer space.
13. **Spoofing;** it is impersonation; presenting self as someone else (the targeted victim)
14. **Unauthorized access;** it is entering computer systems, without authority.
15. **Wiretapping;** It is connecting a device to an ATM/phone line to record information (data) and to misuse the same.
16. **Induction of viruses**

More recently, commercial organisations have used computer forensics to their benefit to fight against a variety of computer crimes including:

1. Bank Fraud
2. Investigations Intellectual Property theft
3. Bankruptcy investigations
4. Forgeries
5. Inappropriate email and Internet use in the work place
6. Industrial espionage
7. Regulatory compliance

26.1.3 Computer and crime

A computer forensics a computer can be:

1. **An object of the crime**

A computer is the object of many crime crimes including:

- It is stolen.
- It is destroyed
- It is corrupted

2. **An instrument of crime**

A computer is used to commit many types of crime including the following prominent ones:

- Smuggling
- Drug trafficking
- Money laundering
- Many types of frauds
- Conspiracies
- Crime planning by criminal gangs
- The list goes on.

3. **A repository of incriminating evidence**

The computers are an ocean of information. The criminal's computer often carries useful information, including the following:

- The names of the members of the gang/associates.
- The information about various crimes committed.
- The names/addresses of contact persons.
- The names and addresses of the persons with whom they carry out their business (drug traffickers smugglers/human traffickers/bootleggers,-money launderers).
- The names of the victims.

26.1.4 Computer Crimes: Motives

Computer crimes are committed for varied motives:

1. **Gains;** bank and frauds, counterfeiting of currency, and money laundering are potent sources of money and computer facilitates the crimes.
2. **Counterfeiting;** of documents, bonds, certificates, shares, and duplication of signatures.
3. Spying.
4. Revenge.
5. Theft of intellectual property.
6. Mischief.
7. Personal Vendetta.
8. Blackmail.
9. Ego.
10. Mental aberrations.
11. Sexual gratification.

12. Espionage; steal vital secret data or information.
13. Destroy, damage, or change vital computerised control systems at various installations.

In view of the above, computer crimes need special attention of all concerned with the criminal justice system or the healthy contribution of the computer forensics.

The criminal has exploited the crime potential of the computer. The investigator must exploit the computer Forensics to detect/investigate/prevent computer crimes.

Computer crimes are of a different species. The losses are colossal. Further, like the universe, they are expanding in all directions with the lightning speed. The investigations are extremely difficult and often the criminal goes unpunished. There is a continued explosion of computer crimes number-wise and in dimensions. The IO, the forensic scientist, the victim, the government, and the public must join hands to curb the menace; otherwise the ***Ghotalas***[1] in thousands/lakhs of crores of rupees not only will continue, but will expand exponentially.

26.1.5 Cyber crimes

Cybercrimes involve the Internet, which is the main distinguishing feature of these crimes. They, like other computer crimes, are often high profile crimes against nations, corporations or individuals with criminal intent for personal gains at the cost of the victim who may suffer mentally, physically or financially. The cybercriminals employ the latest communication mode: SMS, MMS, Facebook, chat rooms, e-mails, Electronic Fund Transfer. Worst still, the hacking activities and information piracies by individuals and nation-states have threatened the security and financial health of other nations/organisation/business houses and individuals.

Pornography, child grooming and copyright infringements are other crimes of top concerns of the public and of the law keepers. Spams are a serious nuisance, torturing computer users.

26.1.6 Characteristics

Computer crimes have the following characteristic features:

26.1.6.1 Intangible Evidence

The evidence relating to computer crime is intangible. The evidence may have been erased, damaged or secreted. The correct facts may not come to light. It may not come to notice even for a long time. Even if it comes to notice, the evidence connecting the criminal with the crime is often not available, or, it is insufficient to permit prosecution or conviction of the culprit.

26.1.6.2 Substantial Losses

The incidence of computer crime, in India, is comparatively low. The main reasons being that the computerisation is yet in its developing stage. Besides the crime is high tech crime. Reserve Bank of India has reported only one crime (up to 1998) in which the overdraft limit was raised for the borrower. This is in spite of the fact that other bank frauds, value-wise and volume-wise, have increased substantially. However, it is a fast-growing crime. In about one decade, the official figures of computer crime have gone sky-high. The IT Minister, in a reply to the Parliament, has given the official figures and the measures thereof taken by that the Central Government of India are:

1. We have their numerous visitations, the latest being (Feb-March, 2018) of Vinod Modi and his associates.

1. According to data maintained by National Crime Records Bureau (NCRB), a total of 217, 288, 420 and 966 cyber crime cases were registered under the Information Technology Act, 2000, during 2007, 2008, 2009 and 2010 respectively.
2. The nature of cyber crime recorded by NCRB included tampering computer documents, hacking, obscene publication/transmission in electronic media, unauthorised access/attempt to access the protected computer system, breach of privacy/confidentiality and digital signature related crimes.
3. A total of 90, 119, 252 and 219 Government websites as reported and tracked by ***CERT-In*** (Indian Computer Emergency Response Team) were defaced by various hacker groups in 2008, 2009, 2010 and January-October 2011 respectively.
4. 219 government websites were defaced by various hacker groups between January to October, 2011.
5. The IT (Amendment) Act, 2008 has been enforced on 27 October 2009 and provides a legal framework to address the issues connected with security breaches of IT infrastructure.
6. The Indian Computer Emergency Response Team (CERT-In) issues alerts, advisories and guidelines regarding cyber security threats and measures to be taken to prevent cyber incidents and enhance the security of IT systems.

The losses to these crimes have not been given in the reply.

The losses in the USA, however, are indicators of the shape of things to come. The losses in term of millions of dollars for various types of frauds are:

- Financial Frauds = > 24
- Software Piracy = > 21
- Sabotage through logic bomb = > 7
- Unauthorised Access (Penetration) = > 8

26.1.6.3 Prevalent Climate

The prevailing working climate in the society facilitates or inhibits computer crimes. The elements of the climate are:

- Checks and controls
- Financial and societal stresses
- Risk standards
- Ethical standards
- Existing laws
- Identification mode of the con artistic
- Prevailing preventive strategy evolved to such crimes
- Efficient or inefficient investigative agencies

Unfortunately, the climate in India is highly conducive to computer frauds. The moral values have gone so much down the drain that even the highest in the society cannot be trusted in financial matters. The only saving grace, so far, had been ignorance of the computer mode of frauds; that has also gone with the wind now.

26.1.7 Investigative Impediment

Computer crimes are different from the usual crime *vis-à-vis* investigations. In the majority of the cases, there are no eyewitnesses, no usual evidentiary clues, and no documentary evidence worth the name. Even the computer misused, may have only erased data, which may be beyond the comprehension of a normal investigator or even of an expert.

Computer crimes are difficult to investigate/control/prevent. The main hindrances, which the IO faces, include:

26.1.7.1 Hi-tech Crime

Computer Crimes are hi-tech crimes. Further computer technology is changing very fast. The normal investigator does not have the proper background in information technology. Special investigators (or team) have to be created to carry out the investigations. The FBI has done it. CBI should do it and create Computer Crime Investigation Cell. The cell should also have private computer specialists (organisation), honest and reliable who can provide the latest technical know-how for the purpose. With increasing computer crimes, it is becoming imperative that each law enforcement agency has such cells.

26.1.7.2 International Crime Global Ramification

Computer crime may be committed in one country. The resultant fall out may be in another country. Often there is no trail. Besides, jurisdictional problems arise. Interpol does help but it has its limitations. The usual crime scene is cyber-space. The Computer terminal may be anywhere even at Delhi or New York. The criminal need not indicate the place. And he does not. Besides, he erases the telltale marks of his handiwork. Often the only evidence he leaves of the crime is the loss to the victim.

26.1.7.3 No-Scene Crime

Computer-satellite-computer link can be anywhere. An input device need not be even a computer. A mobile cell, a notebook or laptop or debit or credit card can do the trick anywhere.

26.1.7.4 Faceless Crime

The criminal has just to drum a keyboard and drums of money are taken away, no personal exposure, no written documents, no signatures, no fingerprints, and no voice. The criminal is truly faceless.

26.1.7.5 All/No-time Crime

The commission of computer crimes is done with the lightning speed at any time of the day. It may take days, weeks, even months and years before the crime is discovered. By that time, the little evidence of the crime also vanishes completely.

26.1.7.6 Inadequate or non-existent laws on national or international level

26.1.7.7 Inadequate international co-operation

26.1.7.8 Inadequate governmental or public defence

26.1.7.9 General lack of information about their modus operandi or handling

26.2 CLASSIFICATION

Some persons have classified Computer crimes as:

1. Internet Crimes
2. Computer Frauds
3. Computer Crimes

Computer is the common factor in all the categories.

26.2.1 Internet Crimes

Internet crimes involve the Internet in their commission. The ultimate effect of the activity is on the computer or the computer user connected to the Internet. The following computer crimes are classed as Internet crimes:

1. Hacking
2. Logic and time bombs
3. E-mail bombing
4. Induction of virus or worm
5. Introduction of Trojan horse
6. Child pornography and child sexual abuse. It is assuming threatening proportions.

   The US police investigated the Wonderland Club, a secret club of those persons who were involved in child pornography, using the international network. It had membership from more than a dozen countries. The communication interchange among the members was through passwords and contents were exchanged through encryptions.

   Police investigation action ended up in about 100 arrests seizure of over 100,000 images. (CH)

   Cyber pornography promoters have adopted many novel ways to expand their nefarious trade. They are using camouflaged pornographic websites, produce pornographic magazines using computers, which are available to their client on the Internet. They can be downloaded to get soft or hard copies of the obscene and dirty images: pornographic pictures, photos, and writings.
7. Hijacking of data; from credit or debit cards
8. Diversion of destination of EFTs.
9. Piracy: art piracy, literature piracy, Entertainment material piracy, software piracy, film piracy, music piracy, piracy of published books. The losses of each piracy run into billions to the original owners.
10. Theft: identity theft, password theft, code theft, information or data theft, official secret data, development project theft, Research data theft.
11. Blocking of service
12. Intrusion (Break-in), spoofing, spams (un-solicited trash e-mails).
13. False propaganda, defamation, character assassination, false rumours.
14. Espionage, eavesdropping, conversion channel.
15. Disruption of services, financial system, air traffic control, communication system, police communication system, army secret communication system.
16. Promotion of terrorism, stalking, threatening, blackmailing
17. Promotion of organized crimes in the same way as promoting business. Its important manifestations are:

- Money laundering,
- Tax evasions,
- Betting,
- Spot-fixing
- Human trafficking, and
- Drug trade.

18. Telemarketing/online sales/investment fraud.

The Internet crimes are also known as cyber crimes, and net crimes.

26.2.2 Computer Frauds/Crimes

Computer frauds involve embezzlement or defalcations achieved by tampering with computer data, record or programme.

Computer crimes involve computers to commit all sorts of crime including: theft, forgery, and counterfeiting. The difference, if any, however, is academic only and has been ignored and the two terms "fraud" and "crime" have been used inter-changeably in the present discussion.

In this chapter, all crimes which involve computers have been discussed. They include cyber (Internet) crimes also. The major types of crimes include:

26.2.2.1 Information Piracy and Vandalism

Electronic information piracy and vandalism have a serious impact on security and privacy. It has vast personal, social, political and economic damage potential through electronic eavesdropping. This is possible through:

- Scanner
- Cables, they act as antennas
- Electromagnetic signals of computers
- Network or Internet

National security information, business information (for black mail) is the usual targets. Information worth thousands of crores of rupees is stolen every year.

26.2.2.2 Theft of Information Services

Theft of information services takes many forms, including the following:

- Mobile Phone Cloning
- Telephone cards counterfeiting
- Illegal access to telephone boards

26.2.2.3 Organised Crime

Organised crime has many facets. Prominent having vast ramifications are: Drug trafficking,

- Child pornography,
- Obscene literature/films circulation,
- Smuggling,
- Human trafficking.

Internet and computers promote them with vehemence.

26.2.2.4 Infringement of Copyrights

Infringement of copyright is one of the most serious computer crimes. Software piracy of entertainment and other programmes prevails on a large scale. In some cases, sales of pirated software are more than of the genuine soft because of the cost differences. It causes heavy losses to the copyright holder.

26.2.2.5 Theft

Theft of equipment, accessories and proprietary items is quite common. Computer as a whole or its parts may be stolen. The software may be stolen. The crime is on the increase. But this is a computer crime, which has the usual parameters of normal theft cases.

26.2.2.6 Wire Tapping

It is a high potential crime. Automated Teller Machines (ATM) are high-risk targets for bankers. Those ATMs where the cables can be approached without being discovered easily are prone to the depredation of the thief/defrauder. The necessary data of the debit or credit cards used in the ATM bank can be recorded and copied and misused through wire-tapping. The con artist steals a lot of money with this stolen data before the fraud is found.

The task involves high tech. The criminal gets hold of the telephone line connecting the ATM with the bank computer. He attaches a wireless microphone to the line and records the signals when a customer is using the ATM. After he leaves the machine, the criminal plays back the signals, tripping the machine to release cash. An accomplice, who is at the ATM, collects the money. The debit goes to the victim whose ATM card data was stolen.

> A few years ago, a telephone operator in Japan tapped an ATM wire and defrauded customers from three different banks of the considerable amount before he was caught. (CH)

26.2.2.7 Data Destruction

The data stored in a computer can be destroyed, contaminated, changed. Usually, the following techniques are used to destroy the data:

- Manual
- Virus
- Logic bomb

Manual technique is used for the immediate destruction of the data. It is equally effective for changing or contamination of the data. It is the same process by which genuine deletion or substitution is done. It is simple. Even a novice can use the technique. Usually, disgruntled employees use it. The current data, important stored data or the command software are the targets of the vandalism.

26.2.2.8 Virus

The virus is an input malicious program, a sort of secret command. Software programmed to replicate itself like a virus to either slow down or destroy the data or functioning of a computer.

26.2.2.9 Logic Bombs

A logic bomb is also a secret software program, which is introduced to destroy the data or the functioning of the computer on the command of this logic bomb. The logic bomb may be:

- Time-targeted
- Data output targeted

In the former logic bomb, the destruction of the data or command module takes place at the time fixed by the logic bomber in the secret command. In the latter, the destruction takes place when the operator processes a particular data or command module. The extent of data destruction depends upon the logic bomb command.

Only computer programmers can introduce logic bombs or viruses. An ordinary computer operator cannot do so. The logic bomber ensures that it cannot be erased easily. Usually, he hides the program within a seemingly harmless item.

> *Two employees, one being a computer specialist, employed by an organisation got dissatisfied with the organisation. They introduced two logic bombs in the system.*
>
> *The first bomb was to erase the command programme of the computer on a particular date. It did. The logic bomb consisted of only 45 lines of instruction.*
>
> *The second logic bomb was to "explode" when the computer was to be tuned to a particular program. It did.*
>
> *Fortunately, the organisation had kept hard copies of all the important data which was critical to restore the computer functioning. But the restoration work cost was over a million dollars and seven days of non-functioning of the computer.*
>
> *Both the employees were traced. They were tried, convicted and imprisoned for the bombing. (CH)*

26.2.2.10 Spy Software

Spy software is utilised to find out Passwords and other vital "entry" information to a computer system. The entry is gained through an innocent-looking item like an e-mail greeting. The message introduces the software and allows the eavesdropping.

26.2.2.11 Money Laundering

In *"Aladdin and the Lamp*" story, the wizard exchanged new lamps for old dirty black lamps. The modern computer *Aladdin* wizard facilitates change dirty black money into white shinning currencies, rupees, dollars, pounds and secreting them in some secret Swiss or other off-shore Banks, without even the bankers being aware of the same by credit cards, super smart cards or electronic fund transfers through any of the machines that accept deposits. "Hawala" like operations, which rocked the Indian political scene in the nineties, would no longer occur. The computer is becoming a big Hawala agent. It transfers with lightning speed the money to any accounts across the borders, to any part of the world, in spite of the fact that the governments may have laws to restrict foreign currency inflow or outflow. It has promoted underground or parallel banking. Political and criminal Mafia are amassing wealth abroad in secret coffers or building castles secretly and with impunity. E-commerce is also making traditional checks and counter checks redundant. Any amount of money can be dumped into an account anonymously in a country, which allows complete privacy to its banking customers.

26.2.2.12 Electronic Funds Transfer

Electronic money transactions are becoming increasingly common. Transfer of money from one bank to another, from one branch to another branch, from one account to another account; or, value for goods received paid electronically is becoming routine mode. Many modes exist:

- Electronic Fund Transfer through computer machines.
- Automatic Teller Machines (ATMs)
- Various types of cards: Credit Cards, Debit Cards, Smart Cards, Super Smart Cards, Optical Memory Cards.
- Internet

Crimes associated with these modes of transfer of money are:

- Diversion of money from rightful to the fraudulent payee.
- Credit cards are copied and data misused.
- Credit cards are stolen.
- Unauthorised persons use lost credit cards.
- White cards are used in place of originals.
- Wires are tapped and necessary data were stolen to operate ATMs account.
- Withdrawals and deposits are manipulated to others accounts
- Telemarketing money is transferred from the victims' accounts without providing the promised goods worth the money.

In one computer operation a dishonest computer operator by instructing the computer got 1% of the interest, from all the saving fund accounts transferred to his account (Salami Transaction). (CH)

26.2.2.13 Electronic Personation

In e-commerce individuals, their writings, signatures, voice, do not figure. It is only through Passwords that the identity of an individual is established. Thus, stolen Passwords are working havoc. Illegal money transfer, diversion, collection and expending are increasing. The anonymity of electronic personation is causing extensive damage. Better electronic identities, through Forensic Biometrics, promise better personation prevention.

26.2.2.14 Hacking

Hackers are intruders, intruding into the computer facilities of other persons or organisations unauthorisedly. The *modus operandi* is simple. They steal passwords and enter into the security system of a computer system. They access the classified information and use the same for:

1. Mischief
2. Gains
3. Destroying data
4. Utilise the paid time on their Internet.
5. Manipulate debit/credit accounts or limits.

Usual hackers are:

1. Students
2. Information technology enthusiast
3. Egoist
4. Zealots of fringe organisations
5. Spies and agents of other governments or competitors

Hackers, like those mentioned above (especially 5), can certainly cause a lot of damage, inconvenience and disturbance in the functioning of the system.

26.2.2.15 Crackers

In recent times, the art or craft of cracking computer has reached a high level. The cracking is achieved through:

1. **Trojan Horse, t**he con artist creates and sends a malicious programme through WWW. It has secret software, to secure entry into the computer system. The computer embraces the programme and thus provides the entry to the system to the hacker.
2. **Password Sniffing:** the cracker taps the wire to get the access password.
3. **Dishonest Computer Staff:** the person, who repairs/services computer, can gain entry comparatively easily. The cracker bribes the operator to gain entry into the system.
4. **Bypassing**: the computer is entered by bypassing the password.
5. **Piggybacking:** the entry is gained by attaching the computer to the connections of the authorised user into the computer system of the target computer and lifting the entry code.

26.2.2.16 Software Piracy

Software piracy is a serious crime. In the USA, copyright holders lose 15 billions of dollars due to this crime every year and the amount is increasing every year. The pirated software cost only the films and disks. Consequently, the pirated software is dirt cheap as compared to non-pirated stuff. Thus, software piracy is a roaring business everywhere.

Software piracy is an expanding crime. The "crime industry" has unlimited scope for software piracy. However, some anti-piracy special software is being developed to meet the menace.

26.2.2.17 Miscellaneous

The variety of computer crimes is increasing rapidly. Other fairly well known computer crimes include the following:

1. Dissemination of offensive (anti-individual, anti-group, anti-religion, anti-ethnic group) materials like pornographic images, Caricatures of individuals showing in bad light, exposing black deeds
2. Phishing; it is an attempt to obtain sensitive information such as user's name, credit card details for malicious purposes. The con artist poses as an honest individual/ business man.
3. **Cyber squatting;** it is registering, trafficking in or using an Internet domain name with bad faith to profit from the goodwill of the trade mark belonging to someone else.
4. **Virus: i**t is a type of malicious software programme (malware), that when executed, replaces itself by modifying other computer programme and inserting its own code.
5. **Botnet;** it is a group of computers connected in a coordinated manner for malicious purposes. It is used to transmit malware, spam or attack other computers.
6. Distribution of offensive literature or other material.
7. Sales and investment fraud.
8. Illegal interception of telecommunications.
9. Stealing telecommunications services and telecommunications piracy.
10. Fake profiles on facebook.
11. E-mail account hacking and email scams.

12. Music piracy.
13. Electronic vandalism, terrorism and extortion.
14. Vishing.
15. Telemarketing fraud.

The list goes on. There is no end to the ingenuity of the computer con artist. He is offering new fare every day. We should check the menu carefully so that it is not too costly and we do not have to pay a heavy price for his ingenuity.

26.3 COMPUTER CRIMINALS

Who are computer criminals?

26.3.1 Employees

Information technology is highly technical. Those who are to use the technology must not only know how to handle it, but they must also know their pitfalls and evasions. Unfortunately, the management-employee relationship, based upon trust, no longer prevails. Hence, checks and balances must form an essential part of the system.

Disgruntled employees, ex-employees, temporary employees who are associated with computers often succumb to the goddess of the quick buck. Besides, negligent and highly obliging employees also contribute heavily toward computer crimes. They fall prey to the charm of the con artist easily.

The honesty angle of the employees at sensitive posts, at promotional stages and at the stages when they are being assigned duties of substantial importance should be checked. The service rules should make it that honesty angle checks are essential ingredients for all employees. The clearing process must utilise the modern scientific and technological aids, including the following:

- Polygraph tests for Detection of Deception
- Psychological stress evaluator test
- Brain printing
- Narco test
- Hypnosis

26.3.2 Computer Experts

Computer programmers and computer consultants; individuals and firms, know that how a little change in the programming (computer commands) can make big changes in its functioning for financial matters or for mischief. The charm of the easy and plentiful money easily influences some of these specialists. They go astray. They "utilise" their skills to make a fast buck. Some of these computer and cyber space experts commit multi-crores rupee frauds.

1. *A life insurance company utilised a computer to collect about 2000 crores dollars illegally.*
2. *Stanley Mark Rifkin, a computer programmer collected 10.2 million dollars in one go.*
3. *Two computer programmers caused damaged worth about one million dollars to the computer system of an organisation.*
4. *Even a non-expert churned out receipt worth over Rs 27 lakhs.*

Unfortunately, computer experts are essential and indispensable. Big organisation must have such experts on their pay-role, but their integrity must be checked periodically. Those who cannot

have experts of their own must choose part-time experts of proven integrity. Wayward experts can prove extremely costly. "Eternal Vigilance" is the word to cope with the specialist crook.

26.3.3 Other Computer Criminals

- Competitors, both indigenous and foreign
- Hostile (even "friendly") foreign powers
- Detectives
- Mischief mongers
- Professional criminals
- Hackers/crackers in varied forms.

It has been estimated that in the USA, number wise, the disgruntled, retired, dismissed, or temporary employees commit about 75% of the computer intrusion crimes.

26.3.4 Handling

It is heartening to note that the Indian government is aware of the positive and negative potential of information technology. It has created a ministry to deal with the various aspects of the cyber world. It is hoped that the technology will receive due impetus to usher in the new era, and the authorities take the necessary step to tackle the high-tech crimes which it is spreading like wildfire.

26.3.5 Laws, Legislation

The Government of India has already enacted an Information Technology Act, as the existing enacted laws in India, were inadequate to deal with cyber crimes. Additions to the Information Technology Act to meet the new problems are done from time to time.

The three main streams of criminal laws are the Indian Penal Code (enacted in 1860), The Indian Evidence Act (enacted in 1872) and The Criminal Procedure Code (enacted in 1973). They did not contain provisions relating to computer crimes. It was, therefore, apparent that new laws had to be framed to permit efficient handling of the cyber crime, the con artist and the intangible evidence thereof. The government has therefore amended these laws also to cover electronic evidence. The ongoing process of amendments of the existing laws continues.

The Indian experience in the actual functioning of information technology is limited. The experience relating to cybercrime is still less. It was, therefore, imperative that the experience of the developed countries, where the crime is prevalent for the past few decades is utilised. The prominent organisations, which have the expertise, are:

1. Organisation for European Co-operation and Development (OECD)

   The organisation has already issued a set of guidelines. They continue updating the same. These publications are useful.

2. The United Nations Organisation (UNO).

   It has published a crime control manual. It is a very useful guide. It is updated periodically.

3. Some countries like the UK, USA, Germany, Japan, and France have framed laws relating to computer frauds. Their experience is of immense help.

Lawmakers in India have utilised the above available expertise in framing the "*The Information Technology Act, 2000*" and its amendments. It is updated from time to time as per our experience and needs.

26.4 PREVENTION

> The watchword for prevention of computer crimes is:
> **"Eternal vigilance"**

Even with the best of laws, with efficient investigating agencies and full national and international co-operation, the successful right conclusion in many cybercrime investigations will remain a difficult proposition in most of the crimes for the reason already mentioned. The emphasis, therefore, should be on the prevention of cybercrimes.

A lot of research is going on to make the system completely secure. Tangible results are also forthcoming. However, the information technology is advancing at such a pace that its security system is not keeping pace with the advancing technology. The con artist pursues and peruses the developments. He tries to be one step ahead of the security system developments. The security specialist, on the other hand, tries to reverse the position. This is a race; the righteous should win.

Philosophically prevention of computer crime is real homework. Secure the target.

The pursuit of the computer criminal, on the other hand, is an unending race in the cyber space against time, against the unknown criminal and against the intangible data in all its varied forms and processes, (input, output, throughput). Prevention, therefore, should be easier, less expensive and more successful.

26.4.1 Access

Only authorised persons should have access to computer. Even close colleagues should not be allowed to use/misuse the computer. The authorities must evolve an adequate system of identification and authorisation of control and access. If more than one person are authorised to work with the same computer, a log of the persons who used the computer with date and time is kept.

26.4.1.1 Passwords

Access to the computer is frequently controlled by passwords. The management should ensure:

- Passwords should be personal, secret and unique. "One password: One person" should be the rule. If an operator changes, the access password to the computer should also change invariably.
- Password should be alphanumeric and longish — not easily guessed/picked up by an unauthorised person.
- Password should be changed periodically. The importance of the data being handled should determine the periodicity. After the specified period, the password should pass off automatically.
- The operator using the password must know (or made to realise) that all work done on the computer with the password will be his responsibility — he should acknowledge this in writing, and cautioned not to pass on the password to any person, however close or intimate.

26.4.1.2 Cards

Authorisation through cards insertion is another or additional security system. The card is inserted in the computer and the computer matches the data to allow/deny access to the

computer/specified data/information in the computer. Unless the card is stolen and misused, the card provides adequate security. Two types of cards are in use:

- **Magnetic strip cards;** they carry the authorisation and identification data in MICR. The computer reads the message and allows/disallows access to its specified data.
- **Microchip cards;**[2] they contain a microchip with memory. The computer does the identification. It allows/disallows access, depending upon match/non-match of the data on the card.

26.4.1.3 Biometrics

Forensic Biometry offers the best passwords. They are individualistic and non-transferable, theft proof and even forgery proof. They can certainly keep an intruder at bay.

Access through biometrics data is the most secure in-thing in data protection. It permits access to the computer only to the authentic user. Iris/Retina images, fingerprints and voiceprints are being utilised for the purpose. Fingerprints are more popular. They are individualistic and hence offer excellent security against the intruders. Their complex nature, however, has been the bane for their universal adaptation so far. However, researches are removing the impediments. It is hoped they are used on a large scale in the coming times.

26.4.1.4 Secrecy

There is enormous data in the computers. Often a user needs only limited data for his *bona fide* use. Whenever possible a user should have access only to the relevant data. The other data should not be accessible to the user of other data files. Passwords can safeguard the data against the unauthorised intruders.

26.4.1.5 Integrity

It is essential to preserve the integrity of the data stored in the computers. It should not be possible for an intruder to alter, destroy or contaminate the stored data. The following steps help:

1. The routine computer workers should have one way computer terminals, so that the operators should not be able to alter or erase the data in the computer.
2. The operator should not abuse or allow the abuse of official computers for personal purposes.
3. The operator should use only authorised data.
4. The operator should alter only authorised data.
5. An opened computer is not left unattended.
6. All changes in the vital computer data should be authorised/supervised at least by two persons. The data should be checked before and after the changes in important cases.
7. Alterations of data include additions, deletions, modifications, creation, storing and transport of data. The work must be trusted not only to competent persons, but they should also be highly trustworthy. The supervisor must check the work.
8. The operator must be assigned the duties/responsibility in writing.

2. A chip card is a standard-size plastic card that contains an embedded microchip. The chip encrypts information to increase data security when making transactions at a chip-enabled terminal.

9. The working instructions are given in writing. A certificate that the official has been read/understood them is obtained. The certificate helps to fix responsibility and accountability in case something goes wrong.

26.4.1.6 Staff

The most important entity for security against computer crime is the proper selection and training of the operators. The integrity of staff employed in computer work should be above board. In addition, they must be intelligent, experienced and dedicated to their work. Further, they must be checked periodically for their integrity through scientific methods, as a part of the system, routinely. A person may be highly intelligent, extremely efficient, yet if his integrity is doubtful, he is positively a potential source of serious trouble and hence a great liability to the organisation.[3] There should be stringent rules and practical action modes to keep an organisation free from the dishonest employee at all levels. The importance of this aspect is apparent from the fact that the staffs commit 75% of the computer crimes or they are committed with their collusion. The following steps keep the bunco at bay:

1. Create security consciousness.
2. Screen, for security, even the highest, who are involved with security sensitive data.
3. Train staff in security management.
4. Do not give sensitive seats to temporary or new employs.
5. Provide an action plan to the concerned; if and when computer crime is committed.

The supervisory staffs have to be computer literate so that they can understand how the system works. They should develop an eye to detect criminal activity and, thus, ensure against the onslaught of the criminal. A drill for the supervisory staff is evolved and carried out periodically to ensure crime-free working of the system.

26.4.1.7 Accountability

It is important to fix responsibility in case a crime is committed. This is possible if exhaustive working instructions and inflexible rules for all prevail and updated periodically. A copy of these rules is provided to each member of the staff who acknowledges its receipt and furnishes a certificate that he has read and understood the rules. The staff must realise that any crime committed through their access mode or through their computer, is their responsibility.

26.4.1.8 Logging

Logging is keeping the record of the work done on/with the computers. Proper logging helps to find out:

- The time of occurrence of crime
- The nature of occurrence: intentional or accidental
- The possible perpetrator
- The extent and ramification of the crime

Proper logging is the main source of information for ultimate processing of computer crime. It should, therefore, be introduced in the working schedule of the computers, even if new software may have to be introduced in the system.

3. India it has been found that in 64% of the bank frauds bank employees, mostly seniors, is involved.

There are various logging systems for various types of applications:

- Security log
- Transaction log
- Work log

Induction of date, time and user's name are useful, especially when a number of persons use the computer. It is not a necessity in personal or standoff types of computers when only one person is using them. The information is still useful if an unauthorised person handles/mishandles the computer.

The supervisory staff must check periodically that the logging is being done properly and that no unauthorised activities/work has been done on the computer.

New generation of computers, provide the time data itself.

26.4.1.9 Encryption

Computers are being utilised extensively to transmit information, entertainment materials, teaching materials, and messages through network and Internet, through cables, microwave transmitters or through satellites. The transmission and receipt of these messages are increasing progressively. It can be misused by the unscrupulous if it is not protected. Coding has been extensively utilised to keep the information confidential and secret. Encryption technology to code the messages is, therefore, the necessity of our time. The only alternatives to encryption are:

1. **Dedicated lines**; they are too costly especially for long distances. They are being used for Local Area Network only.
2. **Special modems**, two modems work in tandem, one at the dispatch site and the other at the receipt site. They recognise signals from each other and thus, messages are conveyed.
3. **Dial back facility**, in this mode the information is transmitted only when the party at the receiving end dials back for the message.
4. **Optical fibres**; for local area network if, instead of usual cables optical fibre is used, the messages can be protected from wire-tapping. The optical fibres do not emit electromagnetic rays. It prevents interruption and misuse of the messages.

Encryption has been in use in other modes of transmission also, especially in the wireless message. The same technology, with additional modern safety features, is used to transmit messages through networks.

26.4.1.10 Physical Protection

Theft, destruction of computers, induction of virus and logic bombs and erasing and alternations of data in computers are hard realities. Besides, accidental fires, arson, explosion, and natural calamities like earthquake, hurricane and storms are also realities, which have to meet with. Computers and computer contents, therefore, need physical protection. It follows the usual safety pattern. Additional safety measures needed for computers are:

1. Duplicate tapes, diskettes of data, command and log systems are preserved at off-site places.
2. The duplicate files are updated periodically.
3. The functional ability and the utility of the duplicates are checked periodically.

The back-up information, thus preserved, proves an invaluable guide in case of computer crimes. They may indicate the perpetrator; permit the assessment of the losses and the reconstruction of the original facility.

Computer crimes in India are yet limited but they are round the corner. They are truly colossal, global and novel. Their investigations are highly intricate and daunting. Prevention is the best alternative to the investigation. It is comparatively easier.

> *In a case of fraud, a forger forged receipts with the help of a computer. The genuine signatures of the victim were scanned on to a computer and the signatures of the victim were printed in blue ink on the receipts worth 40 lakhs of rupees. The duplication and their perfect 'replication' revealed the crime. (CH)*

26.4.1.11 Security Software

The security of data in the computer is of great importance. A lot of research inputs are brought in many software to secure the security of the digital data in the computer. The fraudster is also putting in lots of efforts to cross the security barriers. In fact, continuing war between the keepers and breakers of security goes on. The keepers of law have adopted a multi-pronged approach to meet the menace:

1. Intricate entry passwords
2. Induction of intrusion detection devices
3. Introduction of security savvy procedures and policies
4. Promotion of awareness programs
5. Use of preventive software (fireballs and the like)

26.5 COMPUTER CRIME INVESTIGATION

Investigation of computer crimes where the computer itself has been stolen, broken and burnt follow the usual techniques used in the investigation of crime against property and offers no special problem. The other crimes involving computers are tampering with software either while handling the computer or through the Internet or network. Both types of crimes need a thorough knowledge of computers. Computer experts are indispensable in the investigation of such crime.

26.5.1 Basis of Investigation

Location, collection, preservation and dispatch of the evidence to the Forensic expert are Practical Police Work (PPW), carried out by law enforcement and other agencies. The success or failure of the investigations and trials depends upon these basic processes. They generally follow the general crime investigative pattern, yet because of the high complexity of the technology and miniature nature of the devices it needs certain extra care in handling of the evidence to save the evidence from alteration deletion, destruction, contamination, mutilation or even from substitution. It is essential that the investigating officer understands the basic principles and follow a set protocol to get the maximum and correct information to ensure successful investigations.

26.5.2 Principles

The investigator of computer crimes must observe the following main principles:

1. The scene needs the immediate presence of a police officer. One is, therefore, dispatched at once, on receiving the call so that the evidence at the scene is not lost, stolen, contaminated substituted or destroyed. He performs his tasks,[4] keeping strictly in mind**: "As is, As it was"**:
   - Gets the scene vacated from curiosity hunters and others.
   - Barricade the scene.
   - Save and preserve the fugitive/volatile evidence as far as possible.
   - Assess the men and material needs of the scene for proper handling and inform the IO about the assessment.
2. The evidence and action pertaining to the computer must be handled within the framework of the law.

Data stored in the computer or storage media must remain intact if it is to be presented to the court. A computer involves high technology. It needs careful handling. It brooks no fiddling. The wealth of information, it carries, can get altered lost, contaminated or substituted. The contents in the seized computer should remain:

"As is, as it was."

A technically correct facsimile of the retrieved evidence is prepared and used in all processing, keeping the original data safe.

3. If the data, in the seized computer is required during the investigation, its duplicate is prepared and used. A competent expert duplicates the contents; who ensures and certifies that the original is as it was.
4. All actions (seizure, processing, and storage) in respect of the computer or other like device are properly logged; date wise and time wise, along with the operator name for later verification, if required.
5. While collecting, packing, transporting or storing the computer, ensure that it does not fall or rattle in the container. Pack it in a hard container with proper padding.
6. The identity (*vis-a-vis* the crime), authenticity, integrity and continuity of the chain of possession of the evidence seized must be beyond reasonable doubt, through proper documentation. Proper inventory on the label tag and a properly secured package of the evidence goes a long way to maintain the identity/integrity of the seized computer (or other evidence).
7. Computers have volatile (unsaved) data in RAM. It gets lost if the computer is closed before saving the data; ensure it is saved.
8. If there is some data on the screen of the monitor, it is photographed.
9. Computer crimes are new to India. An average investigating officer has no basic knowledge no training, no practical experience to perform the tasks of handling the computer at the scene, or the evidence thereof. It needs a competent Computer Forensic Expert. The investigation, therefore, needs **S**pecial **I**nvestigation **T**eam **(SIT**) to ensure proper investigations**.** SIT should consist of:

4. See chapter 4 for discussion on the Scene of Occurrence.

- **Chief Investigator; h**e is the team chief. He should be an experienced police officer. He will have the over-all responsibility to assemble the desired (and pre-fixed) team, assign duties to the team members and oversee that the team, individually and collectively performs their duties efficiently and competently. He writes a report on the examination of the scene of occurrence after completing the examination of the scene.
- **Documentation Officer:** He has to be a technician of a high order to document the work done at the scene. Videographic and photographic coverage of the scene and the evidence thereon is his main task. Preparation of a site plan [sketch(es)] of the scene including evidence thereon may be his additional duties. His photographic coverage must show the configuration of the various units and location sites from where the evidence is seized.

  Sometimes the services of a draftsman are requisitioned for preparing the site plan, especially in expansive and important scenes.

  Chief investigator himself write the textual description of the scene for documentation, usually.
- **Computer Forensic Expert;** he helps **s**eizure of a conglomeration of the computer setup and other related evidence. A competent computer forensics expert should form part of the SIT to guide the dismantling and collection.
- If the technical staff of the company manufacturing, installing and/or maintaining the installations is available, their services are obtained for the best results. Nearby outlet of the computer system/device should invariably be located, checked and services requisitioned whenever possible.

26.5.3 Action Protocol

The chief investigator takes over from the first police officer on reaching the scene. He plans the action protocol for the SIT team, guides, controls, and monitor the work. He takes a round of the scene and checks the first police officer's assessment relating to the needs of men and materials and augments SIT if found necessary.

The action protocol is to:

1. Document the location of the scene through video, still photography, sketches and descriptions.
2. Record the configuration of the computer assembly through photographs, sketches and written description.
3. Photograph the visuals on the screen. Save the unsaved contents of the computer.
4. If the computer is on, it needs immediate attention. It has to be shut down. The computer expert decides the shut down mode. It may be by pulling out the power plug or through the operating system of the computer. It has to be done at the earliest to prevent any malware to continue tampering/destroying the evidence.
5. Record the condition of the evidence and condition of the place of recovery. In some cases, the device is found damaged. The factum is recorded carefully. The cardinal principle is the evidence must remain unchanged during collection, preservation, packing, transport.
6. If the collecting expert has done something to resurrect the computer, it is recorded.

7. Seize the computer in the presence of witnesses, observing all other legal formalities as in the case of other evidential clues. Preserve, pack, transport and store the evidence in such a manner that its identity, integrity, authenticity and chain of possession are not compromised.
8. Seize the associated equipment (accessories, CDs, Pen Drives, notebooks, Backup hard disks, floppies, connecting cables) found at the scene.
9. Seize laptop, notebooks, I-Pads and cell phones of the suspect. They may also contain data useful to ascertain the facts of the case in hand.
10. If the computer is "**on**" ensure that the unsaved data is not destroyed. It must be saved and recorded before any other thing (pulling out the power plug!) is done.
11. Collect extraneous evidence (fingerprints, blood or perspiration stains or dirt) on the computer. If the computer is found abandoned and its possession (theft of the computer!) is disclaimed, these traces may link the computer with the user or the culprit.
12. If there is no Computer Forensic Expert in the team, requisition the services of the expert immediately from the manufacturer side or from the departmental digital Forensic laboratory. Most the Forensic Science Laboratories in India have the expertise, though with limited facilities and varied competencies.
13. Obtain the password and other security code, PIN. The suspect may or may not give the same easily.
14. Record the identification data of the computer and its various parts for their identifications. The data may lead to the owner in case the computer is lost or when it is found abandoned or left at the scene or elsewhere.
15. Collect the relevant papers, files and brochures found at the scene. They provide sometimes clinching evidence to help solve the crime.
16. In addition to the above, record:
    - Who seized, collected, packed and sealed the evidence? He must be legally competent to do so.
    - What was the condition of the evidence when it was found?

The investigation techniques of computer crimes are varied according to the nature of the crime. However, certain basic aspects are noted here.

1. The investigator must understand the functioning of the computer, the cyberspace and the Internet. He has to be either a computer technologist. Or, he must procure the services of a computer expert.
2. Even when information sent *via* Internet is deleted or overwritten it can be recovered. It needs the skill to locate and collect it.
3. In crimes involving Internet, the information is distributed on many computers. The information could be coded. The successful investigation is possible only with the help of a computer expert. It is not feasible to collect all the hardware. A selection is, therefore, made in some cases and the computer expert is the right person to do so.
4. The evidence in computer crimes, as in other crimes, consists of the following:
    - Instrument of crime
    - The object of the crime
    - The product of crime

- The *modus operandi*

  They have to be located, identified and collected or recorded.

5. Prevention is far simpler and less costly than investigations.

Computer crimes are yet limited in India. However, the state of affairs cannot continue for long. Computers have unprecedented potential for unlawful gains, for mischief and for excitement. The potential has dawned upon the criminals to computer crimes. They understand its mechanics and its potential, they are letting loose hell on earth. Bank frauds, money laundering. Narcotic trades and cyber terrorism are some of the big fat hens. More are coming. The law keepers must gird up their loins and fight the daunting new crime, preparing themselves to fight and maintain control over the ongoing and the fiercer onslaught of the menace.

26.6 FORENSICS EXPERT INVESTIGATIONS

Fig. 26.2
A write Blocker prevents Additions/Changes to Hard Disk

Computer forensics investigations involve high computer technology. Computer technologist has to know not only but he has to understand the mechanizations of the computer forensics criminal and to tackle his depredations and evidence thereof to pin him with the crimes.

The depredation work is highly specialised and so is its counteraction. They will just be mentioned. Details are beyond the scope of present discussions.

Computer forensic investigations process is done on the duplicate data acquired from the original. The latter is not used as it has to be produced in the court in its original form. The advent of equipment and software for acquisition has made it possible to work with the duplicates.

The investigation follows the usual standard digital forensic processes:

1. Acquisition of the data from the computer.
2. Examination/analysis of the data.
3. Submission of report on the findings with reasons and illustration. 26.6.1Tools and Techniques

26.6.1 Tools and Techniques

A number of open source and commercial tools have come up for computer forensics investigation. Typical forensic analysis includes a manual review of material on the media,

reviewing the Windows registry for suspect information, discovering and cracking passwords, keyword searches for topics related to the crime, and extracting e-mail and pictures for review.

Some of the tools and techniques used are:

1) General tools
2) Disk tools and data capture
3) Registry Analysis tools
4) File viewers
5) File and data analysis tools
6) E-mail Analysers
7) Internet analysis tools
8) Encryption decoding tools
9) Password cracking tools

The list goes on.

The main types of problems are:

- Acquisition of volatile files, deleted files, and hidden files
- Recovery of steganographic data and images
- Identify the stolen data/files
- Password cracking
- Encryption decoding

Numerous tools and techniques have come and the problem is being tackled efficiently. Some of the problems, tools and techniques are discussed below.

26.6.1.1 Volatile data

If a live computer is seized, it is likely to carry volatile data on RAM. It has to be acquired before the computer is shut down; otherwise, the data is lost computer. Google's COFEE tool may be used for the purpose. However, many other tools have come up. Or, it may be transferred to the hard disk.

It is better if the live computer is transported to Computer laboratory for the acquisition of the live volatile data.

26.6.1.2 Deleted files

Most operating systems and file systems do not always erase physical file data, allowing investigators to reconstruct it from the physical disk sectors. Modern forensic software has tools for recovering or carving out deleted data. It involves searching for the needed files within the disk image and reconstructing deleted materials.

26.6.1.3 Data Theft

Stochastic forensics is a method to forensically reconstruct digital activity lacking artifacts, by analyzing emergent properties resulting from the stochastic nature of modern computers. Its chief application is the investigation of insider data theft.

26.6.1.4 Steganography

Pornographic images and incriminating evidence is often hidden in other innocuous images. Computer forensics scientist can fight this by the hashing the file and comparing it to the hash of theoriginal image. The images appear different if it contains steganographic writings/ images.

26.6.1.5 X-Ways Forensics

X-Ways forensics is an advanced work environment for computer forensic examiners. X-ways forensics is more efficient to use after a while, often run faster, finds deleted files X-Ways forensics is fully portable.

26.6.1.6 SANS Investigative Forensic Toolkit (SIFT)

It is a multi-purpose forensic operating system which comes with all the necessary tools used in the digital forensic process. It comes for free of charge and contains free open source forensic tools.

26.6.1.7 EnCase

EnCase is another popular multi-purpose forensic platform with many nice tools for several areas of the digital forensic process. This tool can rapidly gather data from various devices. EnCase can be utilised to examine Active, Latent and Archival data without altering the evidence. It also produces a report based on the evidence.

26.6.1.8 Computer Online Forensic Evidence Ext (COFEE)

It is a tool kit developed by Microsoft to gather evidence from windows system. It can be installed on a USB pen drive or external hard disk. Just plug in the USB device in the target computer and it starts a live analysis. It comes with 150 different tools with a GUI based interface to command the tools. It is fast and can perform the whole analysis in as few 20 minutes.

26.6.1.9 Bulk Extractor

It is another important and popular digital forensic tool. It scans the disk images, file or directory of files to extract useful information. It is faster than other available similar kinds of tools. It is basically used by Intelligence/law enforcement agencies to solve cyber crimes.

26.6.1.10 Registry Recon

It extracts the registry information from the evidence and then rebuilds the registry representation. It can rebuild registries from both current and previous windows installations.

26.6.1.11 Forensic Toolkit (FTK)

FTK is able to make forensic copies and “hash” the evidence, FTK is easy to use and provides an investigator with the ability to view Active, Latent and Archival data without altering the evidence.

New and improved tools and techniques are continuously coming up

26.7 REPORTS

Report contains a detailed summary of all the work done and conclusions reached in computer Forensic investigation of a case. It contains:

1) The experimental Work and tests
2) The examination and observations
3) The data generated
4) The inference drawn with explanations

A good report relies on solid documentation, notes, photographs and tool-generated content. In general, the report may include the following information:

1. Identity of the Computer Forensics expert
2. The institute where the exhibits were examined
3. Referral authority's name and address
4. The name of the officer who brought the exhibits to the laboratory
5. The name of the person who liaises with the expert for the case
6. Date of receipt of exhibits.
7. Date of report.
8. List of items (with their description: serial number, make and model) submitted for
9. The equipment and set up used in the examination
10. Brief descriptions of the exhibits examined and data collected/retrieved (graphics, image, searches, and recovered erased files)
11. Supporting materials such as printouts of particular items of evidence, digital copies of evidence
12. Chain of custody documentation
13. Details of findings
14. Specific files related to the request
    - Other files, including deleted files that support the findings
    - String searches, keyword searches, and text string searches
    - Internet-related evidence, such as Web site traffic analysis, chat logs, cache files
    - E-mail and news group activity Graphic image analysis
    - Data analysis
    - Techniques used to hide or mask data, such as encryption, steganography, hidden attributes, and hidden partitions and file name anomalies

26.9 CASE LAW

26.9.1 Computer Records Confession[5]

> The other aspect on which great emphasis has been laid by learned counsel for the appellant is regarding the manner of the recording of the confessional statement. Evidence of P.W. 131 ASI Kamlesh is of great importance. The confessional statement runs into

5 *Davinder Pal Singh v NCT Delhi*, 2000 Cr LJ 2034.

9 pages. The witness has categorically stated that she had recorded the confessional statement on computer as per the dictation of the DCP. In her cross-examination, she has stated that the time taken was 6 hours. The accused has taken a stand that his signatures were taken on blank papers. As noted above, the accused never made a grievance about any deficiency in the confessional statement till 19-4-1995. That is of great significance. Merely because the confessional statement was recorded in a computer, it cannot be a ground for holding that the confessional statement was not voluntary. Similarly, as DCP has given a certificate in typing when the requirement is that certificate has to be "under his own hand" that is urged to be illegal. It would be too technical to discard the confessional statement or doubt its authenticity on that score. This is merely a procedural requirement. The non-observance does not cause any prejudice to the accused. It has not been shown as to how the accused was prejudiced by the certificate having been typed. The procedure is handmade and not the mistress of law, intended to sub-serve and facilitate the cause of justice and not to govern or obstruct it. Like all rules of procedure, the requirement of record "under his own hand" demands an approach which would be rational and practical and not otherwise. Such minor deficiency, if any, cannot be considered to be a fatal factor so far as prosecution case is concerned. There is one more important aspect which needs to be noted. Admittedly, the accused was a fugitive and was on the run. At the Indira Gandhi International Airport he was arrested for travelling on a forged passport, it has been accepted by the accused in his statement recorded under section 313 of the Code that he had sought asylum in Germany and was deported from there on refusal of asylum. As the records reveal Shri K.S. Bedi (P.W. 130) brought to the notice of Shri B.S. Bhola (P.W. 121) that on 22-1-1995 the accused wanted his statement to be recorded under section 15 of the TADA and requested Shri B.S. Bhola (P.W. 121) to do the needful. Shri Bhola talked to the accused after sending everyone except his P.A. (P.W. 131) out of the room, and asked him whether he was making a statement without any fear or duress etc. He was also intimated that the statement could be used in evidence against him. Despite that, the accused wanted his statement to be recorded. Shri Bhola had given time to the accused till 23-1-1995. The I.O. was directed to produce the accused on the next date at 2.00 p.m. On 23-1-1995 the accused was again produced in the office of Operation Cell, Lodhi Estate. He was asked whether the statement was voluntary or under pressure. After ensuring that all procedures and safeguards have been observed the statement was recorded. A mere statement that requisite procedures and safeguards were not observed or that statement was recorded under duress or coercion, is really of no consequence. Such a stand can be taken in every case by the accused after having given the confessional statement. It could not be shown as to why the officials would falsely implicate the accused. There is a statutory presumption under section 114 of the Evidence Act that judicial and official acts have been regularly performed. The accepted meaning of section 114(e) is that when an official act is proved to have been done, it will be presumed to have been regularly done. The presumption that a person acts honestly applies as much in favour of a police officer as of other persons, and it is not judicial approach to distrust and suspect him without good grounds therefor. Such an attitude can do neither credit to the magistracy nor good to the public. It can only run down the prestige of police administration.

CHAPTER 27

DIGITAL IMAGE FORENSICS

SYNOPSIS

27.1 General 1459
27.2 Importance 1462

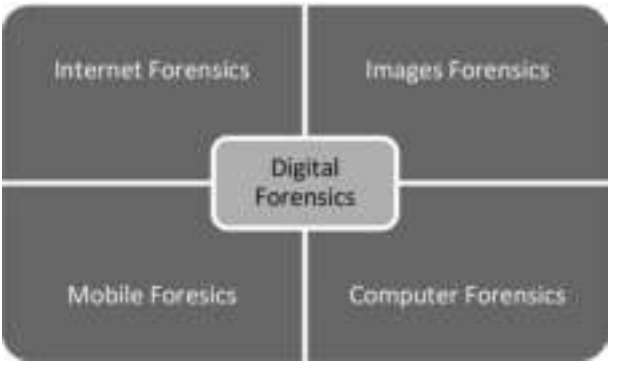

Fig. 27.1

27.1 GENERAL

Photography means writing with light. Forensic photography; therefore, connotes writing with the light of (or about) the evidence used in courts cases. In simple language, it is the photography relating to evidence, the places where the evidence is found, and of persons who are connected with the evidence/crime.

Traditional photography utilises light-sensitive material (on plates, films, paper) for recording the images focused thereon from objects of photographic interest through camera

lenses. The light from the object falling on the light sensitive materials brings in a chemical change in the material. The extent of change is relative to the intensity and amount of light energy, which falls upon the site or the format from where the object being photographed. The images formed at this stage are invisible (latent). The format carrying the latent image cannot be exposed to light as the residual light-sensitive material, on exposure to light, undergoes the same change and mars the image.

The images so produced are called negatives because the brighter parts of the photographed object appear darker and the darker parts come up in the lighter shade on the format. The negatives are made visible by developing and fixing them by chemical treatment in darkrooms before they can be seen.

The negative is used to print the photograph in natural shades of the object. The final photograph is appraised in court.

The traditional photography ruled the roost till recently. It still continues but it is falling out of grace rapidly. Many firms who have not adopted the new technology of digital photography have gone bankrupt.

Digital photography has taken the world by storm and almost literally uprooted the old order completely. Digital photography had its birth pangs in the initial stages. The inferior images at that stage brought in a lot of criticism and rightly so. However, continued developments have brought the image quality at par with film photography. Digital photography has come to stay in the image world with vehemence and has been adopted, nay grabbed, both by the professional and the non-professional.

It has come up of age now.

Digital photography is a completely new concept of writing with light. It has dispensed with:

1. **No chemicals-based processes**; light-sensitive films/photographic paper for capturing the images; and the satellite chemicals used to develop, fix or print photographs are not needed in digital photography.
2. **Dark room studio is no longer** required in digital photography.
3. **Time Lag:** there is no time lag to check the picture taken. The results are checked within a fraction of a second! A second snap can immediately replace the defective one. Images in the digital camera can also be viewed/reviewed on computer or TV. This facet of digital photography is of great value in Forensic science.
4. **Necessity to reload at crime scene:** the camera's light sensor can take hundreds of photos in one go and its memory card can store them in a way that is easy for retrieved/reviewed without fuss. With film camera reloading is needed after 24/36 exposures (snaps).
5. **Identification data chit:** the metadata can be inserted in the photo at the time of printing with the computer.
6. **Camcorder:** some digital cameras play a double role**;** they can function both as a camcorder or still camera. The former role is indispensable to document the scene through video filming.

The advantages of digital imaging over traditional film photography are overwhelming and include:

1. **Image processing;** it is easier, quicker and permits multiple modifications of the image. Colour, contrast/size manipulation are done with ease. The induction of the editing in the camera itself gives colour-balanced image itself.

2. **Minimal ongoing costs;** sophisticated digital cameras are costly. But it is one time investment. Ongoing cost is minimal. Storage and transfer of photographs are both time and cost-effective.
3. **Permanence of colour;** the colours of the images, unlike that of photographs, do not fade with the passage of time: an important advantageous over the film photographs. However, they can be deleted accidentally or by a mischief monger, when they are in the cameras/computer.
4. **No quality loss;** the digital image can be copied from one digital medium to another without any quality loss.
5. **Anti-vibration function;** some digital cameras have anti-vibration device in the camera itself. It obviates the necessity of a camera tripod stand. However, tripod stand should be used in some situations like the crime scene.
6. **Small size sensor;** the picture taken can be checked within a fraction of a second! Instant review!
7. **Transfer;** images can be transferred, copied, e-mailed from one digital device (computer) to another with no cost or quality loss.
8. The cost of snaps, prints or storage is minimal.
9. **Viewing on TV;** many digital cameras now include a connector (and cable) to allow the display of photographs to an audience using a television set.
10. **Processing** is not only easier but it is also quicker. More efficient tools and techniques are helping the process.
11. **Editing of d**igital images in the camera/computer offers tremendous modification possibilities which are more aesthetic, quicker and easier *vis-à-vis* film photographs.
12. **Metadata** identifies photographic data. In digital photography the case data (FIR, PS, Date, and IO's name) is the metadata of a photograph taken relating to that case and the photograph data (camera, speed, flash also metadata) is the meta data. It can be inducted easily in the photograph at the printing stage. It is not possible in film photography.

Recently advances in digital imaging have brought digital cameras that not only compete with the best film cameras, but some of them even surpass them also. In fact, other advantages in digital imaging are so overwhelming that the film cameras are being replaced by all and sundry, most eagerly by the professional photographers. The 16 megapixel models can produce detailed images that are considered better than 35 mm film images.

Roger Clark was a photographer working in scientific imaging at the time he came up with this "film crossover to digital" has made a chart. He's looking at the images produced by cameras as young as the Canon 1Ds Mark II, which came out in 2004. Cameras today (2019) are dramatically better in noise, and of course, some have more than doubled the 20 megapixel resolution at the top of his chart. He has got some of the best films ever made, resolution-wise, at around 16 megapixels in practical terms.

There are some, real or imaginary, disadvantages in digital photography (high consumption of batteries, for example). However, they are few and researchers are after them. They are being overcomed.

The induction of digital photography in the criminal justice system has been slow because of many taboos. But now, the law enforcement agencies are ardent followers of the technology.

27.2 IMPORTANCE

Photography is extensively used in Forensic and police science because it provides realism in the presentation of evidence and psychological satisfaction to all concerned that they have viewed (and checked) the evidence personally. In some branches, it is indispensable. For example, in recording the scene of occurrence (SOO), in documentation of the criminal's or victim's identity, in recoveries, in the evaluation of disputed documents, in the presentation of the identity of the minutiae and in the demonstration of the common or different sources of the striations or other evidence one just cannot do without photography. Photography is being used in Forensics and practical police work, for over a century now. Important applications are:

- Documentation of the scene of occurrence
- Identification of the criminals (portrait or mug photograph)
- Identification of the victim and recording the injuries.
- Fixing the position of the evidentiary clues at the crime scene/other sites and their spatial positioning *inter se.*
- Recording evidence located through UV, IR and X-rays.
- Capturing the action of the culprits in mob violence, riots, vandalism (Videography!).
- Recording/preserving of perishable evidence.
- Recording latent/patent marks of all sorts (e.g., finger, foot, tool, or weapon marks on various articles).
- Illustrating evidence in courts to show common (or different) sources of origin. Examples: documents, fired ammunition, tool marks.
- A sting operation in corruption cases, in action.
- Surveillance photography.
- Necropsy and Mortuary Photography.
- Preserving the scene "live" (videography) and presenting it in the courts

The list goes on and on.

The film photography has served the police science and forensics for a long time, in diverse situations. The advent of digital photography is providing a better service: more comprehensive and less cost and time effective.

27.3 NATURE

There are many devices for the creation and recording of digital images. The prominent and common ones are:

- *Digital Camera*: It is the most important device for digital imaging in forensics. It is also nicknamed Digicam.
- *Scanner*: Scanners are used routinely and extensively to get digital images of documents and to convert photographs into digital form in Forensics (and other fields).
- *Computer Tomography*: It is a technique to get and record cross-sectional images in digital form. It is used in medical studies.

Scanners and computer tomography do not involve digital cameras.

Digital photography employs the following tools and techniques:

27.3.1 Digicam (Digital Camera)

Digital cameras are of many types and brands. The most popular digicam is the cell phone cameras which have made digital photography not only a household affair but has literally become a child's play also. The quality of the images obtained with cell cameras is almost always poor except in costly cell phones. They are not used in professional photography. Some costly cell phones have high quality software.

Professional Digicams vary tremendously in quality of the images produced. 'Point and shoot' types of cameras are convenient but they are not suitable for professional work of the media persons or for police or forensic work. Professional Digicams have to be special so that they can produce images comparable in quality to film photographs. The DSLR generation of the Digicams meets the challenges adequately. A newer innovative Digicam generation has come up which has dispensed with the reflecting mirror in the cameras.

Most of the digicams are meant for taking still images but some of them can take videos and record sound also. These dual duty performers are an asset to the investigator at the crime scene.

The professional photographers using DSLR cameras widely. The cameras have generally the following sub-systems:

1. **The Optical (lens) System:** In digicams the optical systems are similar to the systems used in film SLR cameras.
2. **The Shutter and Diaphragm:** the **gadgets in** DSLR correspond to those found in SLRs in film cameras.
3. **Image Recording:** Digicams use light sensitive sensors. There are two varieties:
   - **CCD** (Charged Coupled Device): CCD sensors are used more frequently than CMOS sensors.
   - **CMOS** (Complementary Metal Oxide Semi-conductor). They capture the image impinged on them.

The image captured in light sensors gives the image in digital data. The process modes offer many advantages.

4. **Images Storage:** A Digicam stores the recorded image in a digital data file, a memory card, which may be either in-built in the camera itself or it may be detachable and replaceable. The card is usually a solid state flash memory device. There are other systems for storing the information (mini-CDs, Floppy disk, CD-RWs), but flash memory is more frequently used. The systems used in digital photography are JPEG and TIFF file systems. It is always advisable to transfer the images from the camera to a computer at the earliest and store the images there.

   The whole process of recording and storage takes only a fraction of a second. The image is ready for viewing, reviewing and for final decision to keep it or delete it and to take another shot.
5. **Image processing:** The digital image, once recorded in the memory card, is ready for further manipulations. Some cameras allow some manipulations by themselves but processing in its varied forms is usually carried out in a computer. The following processes are routinely performed to bring out the best of the image:
   - Contrast enhancement or reduction
   - Editing and cropping (trimming) to remove unwanted parts from the image
   - Size manipulation

- Colour modifications
- Transfer to email, Facebook
- Merging the images
- Segmentation of the images
- Printing the images on any document site.

The digital image can be manipulated, displayed, printed, stored, transmitted, and circulated to all, in a jiffy, using internet and computer facilities. They are being used extensively in e-mails and Facebook, home pages, E-mails.

(a) Modification Possibilities

Digital images offer tremendous modification possibilities which are more aesthetic, quicker and easier *vis-à-vis* film photograph.

Some counsels object to the presentation of evidence through digital photography. They point out that in the absence of negatives (as in film photography) the authenticity and admissibility of the digital images in courts is doubtful because digital photographs can be easily manipulated/modified/replaced and distorted. The testifying expert has to vouchsafe their authenticity and integrity. His certification has to be accepted like that of bio or chemical evidence expert. In USA, the federal laws (rule 101 of Rules of Evidence[1]) are quite clear on the point. We have to adopt the same view towards digital photographic evidence.

The author has been presenting digital photographs in various courts including High Courts now for decades. Only in one court, however, the counsel objected to digital photographs. The author certified their authenticity on oath and also furnished a CD of the un-manipulated snaps taken from the original. (CH)

27.4 QUALITY CONTROL

There are a number of factors (given below), which influence the quality of the images captured in digital photography. Out of these, the first four factors hold good even for film photography. They, therefore, have not been discussed in the present discussion**.** The others have been discussed briefly.

1. Skill of the photographer
2. Photogenic quality of the object
3. Lighting of the object
4. Lens system
5. Light Sensor
6. Image processing devices

1. This Rule of Evidence relates to the Contents of Writings, Recordings, and Photographs. They include magnetic, mechanical or electronic recordings. The Rule states that if data are stored in a computer or similar device, any printout or other output readable by sight, shown to reflect data accurately, is an "original." A "duplicate" is defined as a counterpart produced by the same impression as the original...by mechanical or electronic re-recording . . . or by other equivalent techniques which accurately reproduces the original. A duplicate is admissible to the same extent as an original unless a genuine question is raised as to the authenticity of the original or in the circumstances it would be unfair to admit the duplicate in lieu of the original. This means a photograph can be stored digitally in a computer, that a digital photograph stored in a computer is considered an original, and that any exact copy of the digital photograph is admissible as evidence.

   Unless the photograph is admitted by the stipulation of both parties, the party attempting to admit the photograph into evidence must offer testimony that the photograph is an accurate representation of the scene. This generally means that someone must testify that the photograph accurately portrays the scene as viewed by that witness.

7. Pixel count
8. Memory card
9. Dynamic Range
10. Output Devices

27.4.1 Light Sensor

The change from film photography to digital photography starts with a light sensor — a device that captures the image, in varying intensities of light, in digitised data. The light sensors are essential part of digicams.

The main criterion, which determines the quality of the image, is the resolution of the pixels on the sensor. The acceptable pixel count for a good photograph is 4 Mega-pixels and above.

A rough value of the pixel count *(P)* can be found easily. If the value of horizontal pixels is *X* and that of the vertical ones is *Y,* then the maximum resolution is:

P = X x Y = XY,

[If *X* = 2400, *Y* = 1800], we have

P= 2400 x 1800 = 4320000 pixels = 4.3 Mega Pixels

Pixel count has a great role in the production of image quality. 4 megapixels are the bare minimum. Some photographers use cameras with minimum 10 megapixels. Still others feel 16 Megapixels are the ideal figure for top quality work.

Pixel count is not the only important factor, other factors are also important. Pixel count for quality consideration of the image is the pixel count of the final processed image and not of the camera format.

As discussed earlier, two types of light sensors are common: CCD and CMOS. The former is more common in digicams.

The size of the sensor also affects the quality of the image captured. Larger sized sensors produce better images.

27.4.2 Image Processing Device

The processing software handles the raw data collected by the sensor and produces a colour balanced picture. The device is important in determining the quality of the captured picture.

27.4.3 Memory Card

The image registered by the light sensor goes to the memory card for storage. It may be a permanent fixture of the camera or a detachable device. In some cameras, both systems are used.

The memory card is a digital memory device. Flash memory is the most common device. Floppy disks, CD-RWs are also used. The quality of the storage software also affects the image quality of the output pictures.

27.4.4 Dynamic or Luminosity Range

Camera systems catch images of objects having a certain luminosity range. If the intensity of light is higher, the brightness in the image will hide the details of the image. Likewise, when the luminosity is less, the darkness in the parts hides the details. In some cameras, the

luminosity range is extended. They provide better pictures with more details on a wide range of luminosity. They are a real boon for in forensics and police photography.

27.4.5 Output Devices

The main output device in digital photography is a computer. A high quality laptop meets the need admirably. It helps perform a number of functions and manipulation of the images:

1. Storage of images
2. Editing
3. Dimensional changes in images
4. Trimming, cropping
5. Contrast changes
6. Colour or brightness changes
7. Segmentation of the images
8. Transfer of images to other digital devices
9. Printing of the images on varied formats with the help of a printer

The camera, the computer, the CD-Writer, and Printer should all be compatible with one another to carry out the above functions.

27.5 APPLICATIONS

Digital imaging substitutes film photography technology and provides images in all those fields of police and forensics work where film photography was or is being used; of course with greater efficiency. It is also time and cost-effective. Thus, it is used for all the tasks; stating from the documentation of the scene of occurrence to the presentation of evidence in the court, keeping record of all evidence, of criminals, of victims and events. The main superior features of digital images over film photography are:

- **Videography of the Scene of Occurrence:** The videograph preserves the scene indefinitely and takes it to the court if the court so wants even after years.
- **Presentation of Evidence;** the editing of the digital images, in several ways (segmentation, changes in contrast, brightness, dimensions and synthesis of images) has made it possible for the expert to produce effective demonstrative and easily intelligible illustrations. The courts are appreciating the mode(s).

27.6 TINKERED DIGITAL IMAGES

Tinkering of photographs, also known as doctoring or faking of photographs, is a flourishing trade. It is extensively used in industrial publicity, trade and media, fashion industry, political campaigns, the publication industry, and in the entertainment industry. Additionally, doctored images even land up, not infrequently, in court presentations. It is also a favourite pastime (as well as a profession) of the con artist who indulges in the game for fun, mischief, blackmailing, pornography or even for character assassination. The problem is spreading all rounds and the number of con artists is also increasing with the passage of time.

Photographic tinkering started soon after the advent of photography. The historically famous synthesis photograph was that of the USA president, Abraham Lincoln and his arch opponent (*vis-à-vis* slavery) Calhoun. The synthesis (Head of the president and body of Calhoun), done in 1860, was crude compared to present day con-artists' standards. However,

it was a sensation of the time. There were no present day computers, manipulative software (Photoshop, 3D Max), or digital photography at that time.

Digital photography has changed the completely tinkering scenario. It has reduced the drudgery of the con artist. It is time and cost-effective. Above all, in competent hands, it gives results that can deceive most of the non-experts if not all. Software like Photoshop, 3D Max can produce fake synthesised images that can easily be mistaken for the real images.

Faking of photographs was not frequent or easy before digital photography because the processes involved not efficient. The results were often unsatisfactory. With digital photography, a seasoned con artist can synthesise a fake photograph from two or more images, which can hoodwink most of the observers. The quality of the fraudulent wonder is often so good that only a digital forensic scientist can ascertain whether the given photograph is doctored or not and he can do so only with gadgets.

Scientists have been at work both to create and to decimate the menace. The neck-to-neck race between the two groups goes on. If a solution to one menace is found, the con scientist comes up with a more sophisticated mode.

The Law keepers have better resources in men, money and materials. They have come up with numerous modes and methods, briefly mentioned below. Detailed discussion is beyond the scope of the present works.

The doctoring of an image, especially of a digital image, is done in a number of ways, including:

1. A part of the image is moved from one site on the image to a second site on the same image.
2. A part of the image is removed from the image all together.
3. An image is synthesised from two or more known or unknown images.

The creation of doctored images, to improve their aesthetic value and commercial appeal, is gaining ground. It is creating its space in the commercial world, and it is likely to continue its upward progress.

27.7 PROBLEMS/POSSIBILITIES

Manipulation of images has also created many a situation where a doctored image has brought in legal battles. The digital image expert has to jump into the fray to provide answers to the following types of questions:

1. Is the image under consideration authentic or has it been tampered and its integrity compromised by substituting, removing, or moving some part of the image?
2. Is the given image a synthesised image?
3. Was the given camera used to create part or whole of the given image?
4. Has the doctored image been synthesised from the given images?
5. Can an image be made safe against doctoring?

The doctored image is either a modified image itself; or, it is a synthetic product of two or more images. The synthesis is achieved now by digitising the original photographs if they are not already in digital form. The digitised images are transferred to a computer, if not created thereon itself, having editing and manipulative software. The images are processed further to get the doctored image. They may be changed to grey scale. The unwanted portions from the two are cropped off. The identifying characteristics of the remaining portions are equated

to match with each other in respect of colour shade, brightness and contrast and then the portions are merged together to make a connected whole image, a synthetic doctored image.

Digital image forensics can find answers to the questions, relating to doctored images posed above. The discrimination of a fake image from the authentic image is, thus, possible.

27.7.1 Tampering (Removal or Displacement)

The removal or displacement of a part of the image is called tampering. The tampered part of the image will have vastly different surface characteristics. The process does not introduce new visual artefacts. The following aspects help to establish tampering and the site where it was done:

- The affected area will have a vastly different statistical base.
- Colour filtering and interpolation indicate the change.
- Quality metrics of the affected area are quite different.

27.7.2 Image-camera Linkage

Every imaging device (digicam) is unique, consisting of a unique Lens system, light sensor system with individualistic digital count spread, flash memory and image processing system. They all induct their individuality in the prints they produce. Forensic analyst, by comparing the same with the image as taken through the device (himself or by others), checks the individuality and decides whether the test and questioned images had the common source or not. The important individualising features include the following:

- Sensor imperfections are always present in the light sensors and they are different in different sensors. They give defective pixel count. These imperfections are transferred to the images. Thus, the similarity in the defective pixels indicates a common source (same digicam!).
- Colour filter array interpolation is another data that indicate the common source.
- Demosaicing and radial distortions are generally useful data to indicate common or different digicam used to give the images under study.

The details of the tool and techniques to identify the common source can be perused from the additional reading of section 8.

27.7.3 Synthesised Images

The synthesis from two (or more) images, using computers, to produce a fake new image is the most frequent fraud in digital image forensics. It has been used for blackmail, character assassination, and revenge. It has caused a lot of misery and heartburning.

A lot of progress has been made during the last decade in making synthetic images. If sophisticated software like 3D Max is used for the forgery then it is difficult to detect the handiwork without proper equipment and expertise.

The differentiation is possible because it is not possible to create alike factors or circumstances, which influence the image. The light intensity may vary; the direction of light may vary; the striking angle of the light may vary, the optics of the camera may vary. The light sensor, flash memory and the processing software of the camera vary. Pixel count and pixel noises vary. All these (and more) combine to produce ample discriminatory evidence that is exploited by the digital image experts to differentiate the valid from the forged.

The expert approach uses machine-learning algorithms, modified to suit the original and synthetic images under study. They take the following parameters:

1. A wavelet-like decomposition is used to construct a statistical model of the images or their parts and compared *inter se*.
2. Wave-let coefficient histograms are calculated and compared.
3. The image acquisition processes of the computer generated and natural image are processed geometrically to determine the homogeneity of the image.
4. The sensor noises always exist and they vary from one digicam to another. The study of their pattern is also exploited to discriminate natural image from the synthetic image.
5. Chromatic aberrations permit discrimination of the fake from the original.
6. The synthetic images are smoother than original images. The difference can be detected and the two can be discriminated.

The detection of synthetic images is highly specialised. Only digital image expert should take up the work. The details of the various processes mentioned above are available in the literature (Additional Reading).

27.7.4 Prevention of Tinkering

The prevention of doctoring is assuming importance. We produce a number of images in the court. The court can accept the images as evidence only if they are authentic and their integrity is beyond doubt. However, seeing the images with the eyes alone cannot detect the fraudulent nature of a well-doctored image. It is also not easy to get certification about the authenticity and integrity of the image every time. Prevention of doctoring is the real solution.

One way to do so is watermarking the image, usually in the form of a code number, embedded in the image. The code number is imperceptible. The watermarking is done through software in the digital camera itself. The code number gets printed on all images (photographs) taken with the camera. If somebody tinkers with the image the code number gets disturbed. On extraction and comparison with the original, the doctoring (or natural original state) of the image is established.

Watermarking is essential for those images, which are exhibited in the court. They will ensure their authenticity and integrity. It should be done in all images being produced in the court as evidence as many counsels, rightly or wrongly, question the authenticity and integrity of these images.

Watermarking is also a valuable weapon to track manipulation of the images and to prove the ownership of the image and its contents. It is especially indispensable to prove copyright violations.

27.8 RECENT ADVANCES

A lot of research is going on in digital photography and significant progress has been made in the following aspects of digital photography:

1. Normal photographs can be changed into 3-dimensional photographs. They provide a better appreciation of the evidence. The tools and techniques, however, are costly and have, therefore, yet to become common.
2. Sensors have been improved tremendously. The dynamic range of one to one million is within sight.

The Small Wonder
Crime-savvy Smartphones are sky rocketing Crimes!

28.1 GENERAL

Cell phone forensics is a branch of digital forensics. It is concerned with crimes involving a cell phone. It helps to recover digital evidence or data from a cell phone.

Cell phones possess personal information, such as contacts, photos, calendars and notes, SMS and MMS messages. Cell phone forensics helps to preserve and recover the evidence/data from the device observing scientific principles and legal formalities, without compromising the original evidence in the device.

Cell phone forensic experts often use a cell phone or PDA synchronisation software to "back up" device data to a forensic computer for imaging. Sometimes they process the evidence from the hard drive of a suspect computer.

Mobile phones have ushered in a new era in Digital Electronics not only in personal communications but also in the field of entertainment, music, and education. It is a low cost, low size, low weight device yet extremely powerful gadget for many applications. Because of its high portability, mobility, and mind-blowing versatility its use (and misuse) has spread and is spreading further like wild fire throughout the world. Sheikh Sade, a Persian poet, centuries ago, wrote a couplet in Persian:

Har keh bkamat Kehtar, Bkeemat behtar

(Anything which is small in size, is more valuable.)

Mobile phone has proved the poet's verdict "beyond any reasonable doubt"! Some of the superior models perform functions which were beyond even the imagination a few years ago.

28.2 NATURE

28.2.1 Cell Phone

A cell phone is a complex structure of many parts. The important ones are:

1. **Cell Body;** it houses the various parts and carries the screen and keyboard.
2. **Microphone and speaker;** they make voice communications possible.
3. **Microprocessor;** it handles the miscellaneous activities, of processing the information to perform the desired and the intended acts.
4. **RAM (Random Access Memory);** the software keeps the data created stored by the user.
5. **ROM (Read Only Memory);** it contains the Operating System (OS) software.
6. **LCD (Liquid Crystal Display);** it is used to see the text, images, numbers on the screen.
7. **Wi-Fi;** it facilitates wireless communications.
8. **A Radio module**; it converts the signal into radio frequencies which are relayed.
9. **Bluetooth;** it is mostly in advanced or smart phone only.
10. **GPS;** (Global Positioning System); it enables the person to get the location information of the call(s) and also helps in finding the travel route.

11. **Camera System;** most of the cell phone carry cameras now. They capture images and store them. They have been extensively used to collect covert information and images; for example, in pornography and sting operation. These images have provided devastating evidence in some cases against the culprits.
12. **Detachable Specialized Cards;** the detachable cards carry lots of information of varied nature. They have helped to crack many a case.
13. **PDA;** Personal Digital Assistant file is becoming popular in some smart phones. It usually carries important personal information.
14. Internal memory; it is usually flash memory of NAND or NOR type.
15. External memory; the common types are SIM cards and SID cards. MMC/CF cards and Memory Sticks are other external memory devices.

Newer generations of cell phones have more than one microprocessor. They carry out different functions independently and hence with far greater speed and accuracy. Most of the devices have different shapes sizes and functional protocols. Most of the software gadgets in cell phones provide forensically important information.

28.2.2 Functions

All cell phones, especially the newer models and the smart phones, perform many functions including the following:

1. Computer functions
2. Camera, photography
3. Music
4. Games
5. Calculator
6. Calendar
7. E-mail facilities
8. Internet web browsing
9. A dictionary, a thesaurus
10. E-banking, E-commerce
11. Television, Radio, Recorder
12. A watch. An alarm clock. In fact many persons have stopped wearing a watch. Most of those who do, do so only for its snob value (costly watch!).
13. A personal diary; a personal planner, manager, a reminder, a notes file
14. Potent advertisement medium
15. A public opinion collector on political social or religious issues
16. Data storage
17. SMS and MMS messaging
18. Map, safari, weather

19. Tunes incorporation
20. Various settings software
21. YouTube
22. LOCI (Location Information). Cell phone positioning from geographical data
23. Wireless Network Settings
24. Torch
25. Storage and transmission of personal and corporate information
26. Online transactions
27. Abuse by criminals in the commission of crimes
28. Law enforcement Use of cell phone in handling criminals and crime.

In short cell phone, a marvel of modern science and technology has come up as the most important personal gadget, for the common man, for connecting people, for music, for photography, and for games. For tech-savvy persons, it carries out many more functions routinely. It appears that it or its modified version, might make the laptop redundant or a "bulky" substitute in the coming times.

28.3 CELL PHONE FORENSICS

Cell Phone Forensics, a branch of Digital Forensics, is akin to Computer Forensics. It had to come! With so many uses, its abuses could not remain far behind. They have come in a big way. The cell phone has become a *prima donna*: both of the breakers of law and for the keepers of the law. There is hardly any crime of substance where it is not involved. Both, the perpetrators and he investigators, are using it to the hilt for their cross-purpose tasks. With the increasing number of cell phone crime cases, the demand for Cell Phone Forensics has increased and is increasing both in volume and complexity, exponentially.

28.3.1 Abusers

Almost all criminals misuse cell phone. The abuse is expanding, both volume and dimensions wise. Prominent abusers are:

1. Terrorists
2. Smugglers
3. Sex Racketeers
4. Drug traffickers
5. Saboteurs of all shades
6. Crime syndicates and mafias
7. Pornographers
8. Murderers, kidnappers
9. Illegal betting syndicates
10. Money Launderers.

The small cell phone has become a big boon to the organised crime syndicates. Its abuse by the criminals baffled the police and other law enforcement agencies in the initial stages. They feared that cell phone communication would give the criminal the upper hand. They will get the better of the law enforcement agencies. They were not sure how to deal with the menace. However, now the table is turned. This high tech honcho is helping them in a big way. Forensic scientists have come up with cell phone forensics technologies, which sometimes alone pin the crime to the criminal. They provide a web of information about the crime, the criminal, and the connected environment (men, materials, and situations) that it is not possible for the criminal to wriggle out of the net created by his cell phone.

> *In a recent murder case paramour of the wife and the wife were accused of murdering the husband. The clinching evidence of the killer bullet went against the accusation. It did not form part of the cartridge which had been allegedly fired by the paramour and whose cartridge case recovered from the murder site. However, the telephone contacts of the two accused at the material time placed the accused at the scene of crime site at the relevant time. The pair was convicted of the murder in spite of ballistics evidence supporting their innocence; the court mainly relying on the telephonic evidence. (CH)*

28.4 CELL PHONES EVIDENCE

The cell phones carry a lot of evidence. It must be located, collected, protected, and processed properly. It must not be allowed to get tampered, contaminated, mutilated, substituted, removed, or destroyed by the interested party, by the novice handlers or by the incompetent "experts". The cell phones suspected to carry evidence must be taken into possession (seized) at the earliest with all the required legal formalities, the evidence thereon saved and preserved with the utmost care and alacrity.

The wealth of information which cell phone provides includes the following evidence:

28.4.1 Contacts list

The cell phones have a list of persons (contacts) of the owner or user culprit. Usually, the persons are his colleagues, friends, relatives, business partners or acquaintances. The list may be long or short depending upon the number of contacts of the person (criminal) and also on the capacity of the cell phone. The social background of the contacts provides the social background of the suspect. It is possible that the list may carry the name of the co-culprits who were partners in the crime.

The check on the contacts has been very useful most of the time.

28.4.2 Call Log

Most of the cell phones today have a call log register. It retains all the important information about the calls received, missed or made. The call log of a cell phone reveals who the suspect owner has been contacting at various points of time.

The storage capacity of the cell phones varies.

The information which can be extracted from the call log register includes:

- The phone number of the caller or of the called.
- The name of the person concerned with the call, if the contact list has the name and the number.
- The number of the time the call was made or received.
- The date and time of the calls.
- The duration of the call.

28.4.3 Messages

The message software of cell phones is programmed to receive and to send messages. The messages give direct evidence about the nature of the goings-on *via* messaging.

The message software has the following compartments:

- Platform for writing messages
- Inbox for messages
- Inbox for E-mail
- Draft store
- Outbox
- Sentbox
- Broadcast messages

All the above may have important crime-related information.

The retaining capacity, the maximum number of messages a cell phone can hold at a given time, varies. Both incoming and outgoing messages are retained in the software sites called inbox and outbox. The messages often carry important information:

- Text of the messages.
- Phone number and the name of the sender if the latter is already in the contact list of the recipient cell phone.
- Date and time of the message.

If the number of messages goes beyond the capacity the excess is wiped off automatically. The last message (the oldest one) is wiped off first and then the second last and others in that sequence.

Further, the inbox messages can be destroyed by sending additional excessive (more than the retaining capacity of the seized cell phone) messages from some other phones. It must be prevented as suggested elsewhere.

28.4.4 GPS Software

Some cell phones come with GPS software. The software has the information about the movement of the user. It also indicates the time when the user was at a particular place. Thus, the GPS can, therefore, connect the user with the crime scene and indicates the time when he was at the scene.

28.4.5 Other Data

The cell phone carries other useful data which is provided by:

- **E-mails, received or sent;** the E-mails may reveal the accomplices, the location of the crime scene, action plan, the disposal site of the incriminating articles and the escape plan.
- **Photographs;** they may be of men, materials or places. They may be related to the crime being investigated and thus provide links between the user and the crime.
- **Calendar;** it gives the idea about the activities of the immediate past and of those which the user had planned for the future. The information therein can link the user to witnesses, instruments of crime, places and time of the activities.
- **Notes:** the user may be using the cell phone as a notebook (diary) to record notes on various matters, meetings, places and events, partners in crime and their addresses. The notes, thus, can be useful source of information in criminal investigation, if available.

- **Web Browsing**
- **Cell phone's IMEI (International Mobile Equipment Identity), ESN (Electronic Serial Number):** they are the identification data of the phone. They fix the identity of its owner, when the IMEI and ESN are known.

28.5 EVIDENCE SOURCES

The following parts of the cell phone carry the evidential data. They are checked routinely for information on the cell phone:

1. SIM Cards
2. Memory cards
3. Wireless network settings
4. Smart phone "apps"
5. Internet media
6. Handset
7. Web Browsing
8. Service provider

28.6 CELL PHONE FORENSIC PROCESS

Cell phone forensic process involves the following main tasks:

- Seizure. The investigator carries out this important work.
- Acquisition. It is a highly sensitive and delicate task. A qualified and experienced cell phone forensics specialist handles the task.
- Examination and analysis. The cell phone forensics laboratory staff examines and evaluates the acquired data.

28.7 SEIZURE

It is the work of the investigator. It involves location, collection, preservation and dispatch of the evidence to the Forensic expert. It is **P**ractical **P**olice **W**ork (**PPW**), carried out by law enforcement agencies or by private investigators. The success or failure of the investigations and trials depends upon these basic processes. They generally follow the general crime investigative pattern, yet because of the high complexity of the technology, miniature nature of the device, and delicacy of the device. It needs some special treatment and additional care in the handling of the evidence to save the evidence from deletion, destruction, contamination, mutilation, or even substitution. It is essential that the investigating officer understands the basic principles and follow a set protocol to get the maximum and correct information to ensure successful investigations.

28.7.1 Basic Principles

1. Cell phone is an ingenious marvel of technology. It does not brook fiddle with it. Neither the investigator fiddle with it nor allow anybody to do so. The wealth of information on the cell phone can get lost, contaminated, or substituted. Remember the seized cell phone should remain

"as is, as it was".

2. Cell phone has delicate software. It is prone to damage if exposed to static electricity, magnetic field, excessive heat, moisture or severe shock. They must be avoided while collecting, packing, transporting or storing the cell phones. Pack the cell phone in antistatic plastic or paper hard containers. The cell phone should not rattle in the package.
3. The identity (*vis-a-vis* the crime), authenticity, integrity and continuity of the chain of possession of the evidence seized must be beyond reasonable doubt, through proper documentation. Proper inventory on the label tag and properly secured package of the evidence goes a long way to maintain the identity of the cell phone (or other evidence).
4. All actions (seizure, processing, movement relating to the cell phone, storage) taken must be properly recorded for later verification if required.
5. Cell phone also has volatile memory. It is deleted when the cell phone is put off. The volatile memory needs preservation before the device is switched off. It is either "saved" or copied to computer or other electronic storage device.
6. The Cell Phone Forensic evidence is new to India (not so new now). An average investigating officer has neither the basic knowledge nor the training, nor practically any practical experience to perform the tasks of handling the scene, the evidence or to process it. It needs a competent cell phone Forensic Analyst. The investigations, therefore, needs **S**pecial **I**nvestigation **T**eam (**SIT**) to ensure proper investigations. SIT should consist of:
   - **Chief Investigator:** He is the team chief. He should be an experienced police officer. He will have the overall responsibility to assemble the desired team, assign duties to the team members and oversee that the team, individually and collectively performs their duties efficiently and competently. He writes report on the examination of the scene of occurrence after completing the examination of the scene.
   - **Documentation Officer:** He has to be a technician of high order to document the work done at the scene. Photographic coverage of the scene and the evidence thereon is his main task. Preparation of a site plan [sketch(es)] of the scene including evidence thereon and recording the scene and the evidence may be his additional duties.

     Sometimes the services of a draftsman are requisitioned for preparing the site plan, especially in expansive and important scenes.

     Textual recording of the scene is usually done by the chief investigator himself.
   - **Cell Phone Technician:** Seizure of a cell phone needs some technical considerations. It is essential that a competent technician, well-versed in cell phone technology, guides seizure of the cell phone. If the cell phone is switched off, it needs no action at the scene. It is collected like other evidence. If the cell phone is "'**on**", it needs special treatment so that the evidence thereon is not lost. The technician has to guide whether the cell phone is switched off, the battery is taken out or it is carried in Faraday cage (bag). The cell phone technology of the crime cell phone determines and dictates the safety measures in the collection process.
   - If there is something on the screen it is photographed before further processing.

- If the technical staff of the company manufacturing/servicing the device is available, their services should be obtained for the best results. Nearby outlet of the device should invariably be located, checked and services requisitioned whenever possible.

7. **First Police Officer at the Scene;** the first police officer reaches the scene post haste so that the evidence thereon is not lost, stolen, contaminated substituted or destroyed. It is not always possible for the designated investigator or member of his team to reach the scene immediately. Yet, the scene needs the immediate presence of a police officer. One is, therefore, dispatched at once on receiving the call. He reaches the scene immediately and takes over the responsibility at the scene. He performs the following tasks, keeping strictly in mind the integrity of the evidence:
   - Gets the scene vacated.
   - Barricade the scene.
   - Save and preserve the volatile evidence as far as possible.
   - Assess the men and materials needs of the scene for proper handling and inform the SIT chief about the assessment.
   - Listens to the gossip going around relating to the crime.
   - Detain the suspects/witnesses
8. **Facsimile Evidence;** Duplicate of cell phone evidence is prepared for day to day handling.

   A technically correct facsimile of the cell phone contents is prepared and used in all processing.

   This will keep the evidence in the cell phone intact.

28.7.2 Seizure Action Protocol

The action protocol for the SIT team is planned, guided, controlled and monitored by the chief investigator. He takes over the scene from the first police officer at the scene. He takes a round of the scene and checks the first police officer's assessment relating to the needs of men and materials and augments it if found necessary. He, then, takes steps to:

1. Document the location of the scene through video, still photography, sketches and descriptions.
2. Record the condition of the evidence and condition of the place of recovery. In some cases the cell phone may be found damaged, dipped in some fluid or buried under ground. The cell phone technician may stop further damage or resurrect the device as much as he can, carefully to avoid adding to or destroying the still existing evidence thereon. Anything done to evidence at the scene (or elsewhere) must be recorded.
3. Document the evidence, being seized, collected and packed, including the cell phone, in the same way.
4. Ensure that the evidential value of the digital evidence (or other evidence) is not compromised in the collection, preservation and packing processes.
5. Photograph the visual on the cell phone screen.

6. Take the cell phone into possession in the presence of witnesses, observing all legal formalities as in the case of other evidential clues. Preserve, pack, transport and store the evidence in such manner that its identity, integrity, authenticity and chain of possession are not compromised.
7. Seize the associated equipment and accessories connected with the cell phone: connecting cables charger(s), power adapters, media, (U)SIM, and other evidence relating to the phone should be collected from the scene.
8. Seize laptop or personal computer of the suspect. They may contain excess data from the cell phone stored therein.
9. Locate, collect, and seize detachable accessories (memory cards, (U)SIM). The cell phone technician will be able to identify them. The team members should also be familiar with the various detachable parts.
10. Ensure that the volatile evidence is collected, preserved, or recorded immediately and properly, if the cell phone is **"on"**.
11. Check the cell phone for extraneous evidence (fingerprints, blood or perspiration stains or dirt). Collect the evidence. These traces may link the abandoned cell phone to the user.
12. Preserve the evidence (the varied data) on the phone. The data can be deleted, overwritten or replaced by remote control devices (telephony!). Save it:
    - Ask the service provider to disable the service to the involved phone, immediately.
    - Put the cell phone in a **"Faraday cage"**[1] or in a radio frequency isolated container. It prevents the radio rays to reach the cell phone from outside and thus it will not be possible, ordinarily, to tamper with the cell phone data with remote control.

Fig. 28.2
A simple Faraday Cage

1. It is a device to keep off the incoming calls. It is also known as Faraday Cage (bag).

- Switch off the cell phone. The process washes off the volatile memory.
- Remove the battery of the cell phone. Removal destroys volatile memory. It may also lock the phone.
- Place the cell phone in an area protected from radio rays. The created area may be in a scene of crime vehicle or an area at the Analyst's laboratory.
- Use radio jamming or spooling devices are to shield the cell phone from remote control including outside phone contact.
- Trick the handset by using (UMITS)SIM (Universal Mobile Telecommunication System) Subscriber's Identity Module]. This module substitute action for the real SIM card. The original contents will thus be saved. The trickster, (U)SIM, can be used anywhere.

All these methods have their limitations. The seasoned cell phone technician understands them and adopts the best mode to save the evidence. Removal of battery, if the cell phone does not get locked on removal, is the best mode.

13. In case the correct method could not be determined, requisition the services of the expert immediately from the manufacturer or from the departmental digital data Forensic laboratory. Most of the Forensic Science laboratories have now digital evidence evaluation units, though most of them have limited facilities/ competencies.
14. Obtain the password and other security code, PIN. The suspect may or may not give the same.
15. Collect the IMEI (**I**nternational **M**obile **E**quipment **I**dentity) and ESN (**E**lectronic **S**erial **N**umber) identification data of the cell phone for its identification. The data may lead to the owner in case the cell phone's owner is not known (when it is found abandoned or left at the scene or elsewhere).
16. Preserve, store, transport and handle the evidence on the cell phone using methods and modes which do not compromise the authenticity, integrity, chain of possession, and legality of the evidence.
17. Note down the technical specifications of the cell phone if they are available without disturbing the cell phone settings and disrupting other data. They may indicate the technology (power) and possible contents of the cell phone.
18. Collect the relevant papers, files and brochures found at the scene. They might reveal useful information.
19. Record:
    - Who seized, collected, packed and sealed the evidence? He must be legally competent to do so.
    - What was the condition of the evidence when it was found?

IO's Drill

1. Call in the cell phone expert to the scene at once.
2. Let the expert handle the technical aspects of the evidence.
3. Fix the identity of the phone through photography and documentation.
4. If the cell phone is '**on**', collect, preserve and record the volatile evidence immediately through the expert.
5. Use Faraday bag/RF-shielded box, RF-shielded room for network isolation of phone.
6. Take out the SIM card photograph, document it and prepare a its clone
7. Prepare a Clone of the SIM card (with expert help). Use the clone in place of original in all day to day work
8. Get both logical and forensic extraction from the cloned SIM through extraction and analysis tool with expert help.
9. Parse and examine the data from physical extraction and co-relate it with case.
10. Create images for the various file types or strings of data. (with expert help) and sift the case connected data
11. Prepare a report of the relevant findings
12. Co-relate the findings with other evidence in the case
13. Handle the non-SIM devices through an expert:
    - Consult manufacturer whenever possible
    - Do physical extraction of the cell phone device and examined the parsed extracted data.
    - Extract data from the logical examination

Prepare files from raw images of various files

28.8 PHONE FORENSICS ANALYST

The basic work of the cell phone forensics analyst is to identify the phone in respect of its make, model, service provider, and the user or owner of the phone and to examine and evaluate the contents of the given cell phone.

28.8.1 Identification of the Cell Phone

It is identified from:

1. IMEI (**I**nternational **M**obile **E**quipment **I**dentity)
2. ESN (**E**lectronic **S**erial **N**umber)
3. ICCID (Integrated **C**ircuit **C**ard **Id**entification **N**umber)
4. Manufacturer's label (It carries make and model information usually) and Logo. The information is usually found in the base of the battery cavity.
5. If the phone number is known, service provider can be found. He furnishes a lot of information about the identity of the cell phone.

6. The pattern of settings and filing system of a cell phone is different in different models or makes. The patterns indicate the make and model of the cell phone.

There are websites which give detailed data, photographs about different types of cell phones. They are helpful in the identification. They should be consulted whenever there is doubt about the identity of the cell phone.

If the maker of the cell phone is known, his Website should be checked for information. It will carry detailed specifications and information on various features of the phone.

28.8.2 Retrieval of Contents

All relevant contents of the cell phone are collected and their electronic (and hard) copies are prepared.

28.8.2.1 Retrieval of the Deleted Text

There may be some deleted text from the cell phone which may be important. It isresuscitated, whenever possible.

28.8.2.2 Identity of the Contacts

The identity of the contact should always be checked personally whenever possible or through the phone number available on the seized phone.

28.8.2.3 To and Fro Calls

To and fro calls' information has helped to solve many a crime. These calls can provide information about the contacts. The frequency of the phones to a contact leads to the part played by the contact. In addition, calls indicate:

- the places from where the calls were made through GPS evaluations Thus, many criminals are placed at the scene through the calls.
- the date and time of the contact help to connect the caller and the called
- duration of call(s) often fixed the intimacy of the caller and the called.

28.8.2.4 Exchanged Messages

The contents the exchanged messages can provide important information about the crime being investigated. It should be seized.

28.8.3 Additional Problems

During the handling, examination, evaluation and analysis of the seized cell phone, the major problems which crop up are:

1. How to get at the Password, especially if it is biometric or visual login?
2. How to power the cell phone during collection, transport and storage especially when it is in sealed packet?
3. How to detect, get rid of malicious virus intentionally inducted in the cell phone to prevent extraction and analysis of the data in the cell?
4. What are the best mode(s) or equipment (software) for the extraction and retrieval of data on the given cell phone?

5. How to connect the cell phone to a PC to transfer (copy) the data for detailed study?
6. How to open a locked SIM? (Password?)
7. How to operate a biometric password if the suspect user does not cooperate?
8. How to handle a cell phone carrying malignant program introduced by the abuser to mislead the analyst?
9. How to correct the tampered key command buttons?

These are technical problems. The solutions vary with different brands and models. A seasoned cell phone forensics analyst is able to handle most of them, most of the time. In refractory cases he, however, requisitions help from the cell phone's manufacturer or his agents.

It is always desirable to get the help of the technical staff members of the manufacturer. They know all about the cell phone or can get the information. Further, they assist the investigator to ensure the safety of the evidence on the phone, when the investigating team has no competent Forensic analyst to handle the evidence. They also help the investigator to:

1. Locate and collect extraneous evidence.
2. Render the evidence 'safe' from remote control changes in the phone when the cell phone in "**ON**".
3. Lead the investigator to the owner of the cell phone by providing identifying data of the phone:
   - IMEI
   - ESN
   - Cell phone manufacturer and Logo.

The above information is bonus information to the one he provides after the complete Forensic examination.

28.9 FORENSIC PROCESS

The Cell Phone Forensics starts with the seizure of the cell phone. The first step of the analyst (or of the cell phone technician) is to save the volatile memory from automatic purging, malicious software and external remote attack. The second important step is to ensure the safety and integrity of the data in the cell phone. The third step is to acquire (retrieve) the information/data in the cell phone. The process is called acquisition. It prepares a duplicate (partly or wholly) of the contents in the cell phone. The last step of the analyst is to examine and analyse the retrieved data to fix the identity of the cell phone, to find evidence of a crime, to identify criminal, and to link him with the crime. The analyst uses the best duplication tools and techniques to extract the data on to a blank unused cell phone, computer, or other storage media. He may prepare more than one duplicates of the digital data in the cell phone. The work is carried out at an electronically safe place with modern tested and reliable gadgets to ensure safety/integrity of the original data and to achieve complete acquisition of the relevant data. The last step is to examination and analysis of the data. In the handling process he takes care to:

- Safeguard the integrity of the original contents: no contamination, no mutilation, and no destruction.
- Prevent virus entry into the phone.
- Prevent interference into the contents through remote control
- Label the retrieved data properly for its identity.

The original digital data is not used for day to day work. Its duplicate is prepared and used for examination and analysis. Thus, the original data in the cell phone remains intact.

The analyst job is formidable; many brands in the market, with diverse technologies, volatile nature of some data and induction of corrupting viruses are his big headaches.

Standard recovery principles

(for cell Phone Evidence)

1. Consistency with legal systems
2. The Forensics analyst handling the cell phone evidence has Forensics competence.
3. During/after seizing digital evidence, actions taken should not change the original evidence.
4. Only the person, forensically competent, should access original digital evidence; it is necessary to do so.
5. Documentation of all activities relating to the seizure/access/storage/transfer of digital evidence must be fully documented, preserved, and made available for review, if required.
6. An individual is responsible/accountable for all actions taken with respect to digital evidence while the digital evidence is in their possession.
7. The laboratory undertaking the work is accredited
8. Validation of tools, techniques and training in them exists.

28.9.1 Cell Phone Forensics Analyst

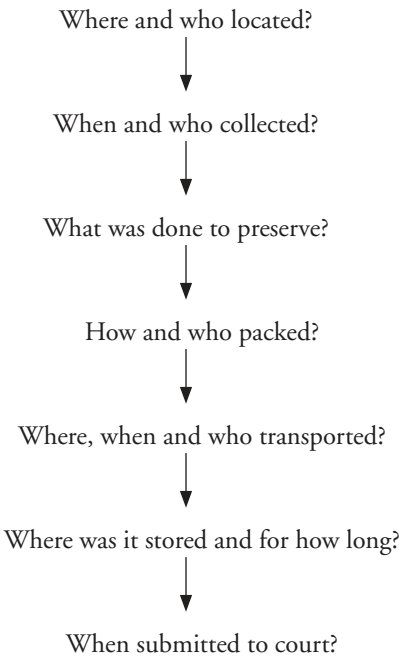
Cell phone forensics analyst has to be exceptionally competent to handle ever newer technologies which are so varied and changing so fast! The analyst must have:

1. A basic thorough grounding in digital forensics.
2. Intensive and extensive training in cell phone forensics.
3. Ample work experience as an understudy with experienced cell phone forensic analyst.
4. An up-to-date laboratory with all the important tools to extract, duplicate the contents correctly and completely and to carry out other tasks relating to cell phone forensics.
5. A fairly extensive museum (collection) of cell phones, their accessories and acquisition tools in his laboratory.
6. Knowledge about the ever incoming developments in cell phone technologies.
7. Extensive liaison with the technical staff of the various manufacturers, cell phone technicians and fellow analysts; whenever possible.
8. Membership of the society of cell phone forensic analysts and participation in cell phone forensic meetings, workshops and seminars.

The day is not far when we may have to have different specialists in cell phone Forensics for different brands of cell phones or for different tasks in cell phone forensics.

Cell phone forensic evidence, as the name indicates, has to be presented in courts. The evidence, therefore, has to be court savvy. It must be:

- clear (unambiguous), concise, precise and easily intelligible.
- presented by a competent professional, with proper basic education, training and experience.
- Based upon accepted and verifiable scientific principles, tools and techniques.
- The chain of custody of the evidence must remain intact (unbroken) from the time of the seizure to the time of production in the court. It is kept in a logbook. The handlers of the evidence must ensure the continuity of the chain of possession of the evidence:



Where and who located?
When and who collected?
What was done to preserve?
How and who packed?
Where, when and who transported?
Where was it stored and for how long?
When submitted to court?

Fig. 28.3
Chain of possession

28.9.2 Acquisition

Acquisition is the acquiring (extraction, retrieval) of data from the cell phone and similar devices and media through photography, imaging or reading. It may be done at the crime scene or elsewhere. However, a cell phone forensics laboratory is the right place. It has better equipment facilities.

Acquisition is the most important technical step. It is simple mental and manual labour in most of the cases. In some cases, however, it often amounts to research (a new model) where new technologies have been used. Liaison with the manufacturer, his agents, or dealers help.[2] They know the new software and hence can help.

2. Acquisition tools and the processed are highly technical and are changing every other day. They have been just mentioned. They need not be understood by the investigation, the counsels and the judge. The analyst has to dive into the original current literature.

28.9.3 Acquisition Tools

The acquisition of data from a cell phone was manual work in the initial stages. Each item of information on the phone was brought on the screen, studied and relevant data photographed for record, for future re-examination or for presentation in the court. The information collected was usually Contacts Lists, Call Logs, SMS, MMS and the cell phone identity data (Maker's name, Logo, IMEI, and ESN).

The method had disadvantages. *Firstly*, all the information in the cell phone could not be reached and acquired. *Secondly*, there were chances that some evidence may get mutilated or lost inadvertently. *Thirdly*, the evidential data could be obtained only in photographs. *Lastly*, the deleted data could not be retrieved by manual acquisition! It was a serious lacuna.

Soon after, acquisition software started coming up. They could retrieve data from a cell phone and copy it on to a corresponding blank cell phone or to a computer. More than one copy of the relevant data could be prepared for detailed study and evaluation by more than one expert, if so required. Software to retrieve the deleted data also started coming up. Now there are numerous softwares which retrieve the evidence in a cell phone.

The following considerations determine the selection of the software for the recovery of the evidence:

1. The software is compatible with the cell phone.
2. It has been tested and used frequently for similar acquisitions from similar devices.
3. It (and the technique) is recognized and accepted by the larger community of the cell phone forensic analysts.
4. The extractions are accurate, verifiable.

The main characteristics of such software are:

1. There is no universal tool which can extract data from all cell phones. Certain tools are brand-specific. They are very effective for the brand. They may prove useless for other brand cell phones.
2. The developments in cell phone technologies are so fast that acquisition ware becomes dated soon after launch. The competent and conscientious cell phone analyst is always on the lookout for the new developments and keeps himself with the top Joneses so that he can handle the latest editions of the cell phone effectively.
3. Particular software may recover most of the data but it does not recover all the data. Consequently, the analyst often uses more than one software to maximise recovery of the deleted or undeleted data.
4. They are time and cost effective.
5. They cause minimum damage to the data, stored in the cell phone.
6. They are mostly commercial and proprietary items in nature.
7. They are mostly automatic.
8. Usually new tools are needed for new updated cell phones.

There are numerous specialised tools with fancy names. But the modifications are so fast that one has to check up the WWW to find the correct hardware and software tool for the given device.

BOUNDARY SCAN is one which is proving quite handy these days. JTAG (Joint Testing Action Group) developed. It is the tool which copies both the volatile and non-volatile memory, though the time taken for imaging is long usually. The technique is not of universal application.

De-soldering of the memory chip, for non-volatile memory, is another mode to extract memory data on the chip. The memory chip thus removed from the cell phone is attached to the memory reader and contents collected. The memory chip is re-soldered to the phone. The process can damage the chip and mutilate its contents.

The tools for extraction of evidence are legion. Among them, the popular ones are:

- **Access data,**
- **Sleuthkit,**
- **EnCase.**

The details of various tools and techniques to extract the data from the memory repository are beyond the scope of this book. Some of the important names of the current acquisition tools and techniques are:

- Hex editor
- Micro systemation XRY
- Access data MPE
- Radiotactics
- Oxygen Forensic Suite.

28.9.4 Acquisition Processes

The acquisition modes of cell phone contents vary. The current ones are:

- Manual Acquisition
- Physical Acquisition
- Logical Acquisition
- External Memory Acquisition
- Internal Memory Acquisition
- File system acquisition
- Brute force acquisition

28.9.5 Manual Acquisition

The manual retrieval of digital data, as already seen, is the simplest and the first mode used for the recovery of contents in the cell phone. The cell phone contents are brought on the screen, item-wise, one by one, scrutinised and the evidentially important data is photographed. The retrieved evidence is in the form of photographs which can be understood and appreciated by all concerned. The acquisition mode has certain disadvantages.The manual acquisition mode is used rarely; usually where the workload is limited and retrieval software is not available. Or, some evidence is not amenable to automation. Use of videography, however, to record the screen images, one after the other, has come handy for detailed study and presentation of the evidence on the cell phone.

28.9.6 Physical Acquisition

In physical acquisition, the Forensic Analyst uses high tech software to extract digital data from the cell phone. The software retrieves the entire data directly from the memory (flash memory), part by part, and copies it on the desired format (computer or blank cell phone).

Physical Acquisition software can also extract deleted files as well as the remnants of the deleted data.

28.9.7 Logical Acquisition

Logical acquisition is used to retrieve evidence from logical stores (directories, files). The process copies the stored files and directories in the logical store, one by one directly on to a computer *via* the manufacturer's interface provided for synchronising the contents of the phone with the computer.

Logical retrieval can resuscitate only those deleted files which are marked deleted and are not overwritten.

28.9.8 External Memory Acquisition

External memory software may have mainly cards. Thus we have SIM, SD, MMC and CD cards. In addition, there is a memory stick. The memories are locked via a switch present in the cell phone at the earliest to prevent changes in the same. External write-blocks are also available to prevent changes in memory.

The contents of the external memories can be easily copied through software (card reader) developed for the purpose. In some, the memories can be copied directly on to a computer without software.

It is possible to read deleted files in the external memory devices.

28.9.9 Internal Memory Acquisition

Acquisition of the internal memory (mainly Flash Memory) is the toughest nut to crack. There are a number of tools. For example, system commands are used to extract information. They are also used to retrieve volatile memory.

Flasher tools are another category of tool wares that can extract memory (Flash memory!). These tools are mostly available with the manufacturer and are useful for their brands.

28.10 ANTI-FORENSIC SOFTWARE

Manufacturers are inducting stringent safety measures increasingly to protect the contents of their cell phones. The safety software is being introduced in the memory cards. For example, biometrics passwords, visual login, token-based entry, malicious programs, faulted key functioning, remapping the card controlling the functioning are all anti-forensics, creating problems. These additions are obstructing the extraction work of the analyst. However, liaison with the company can solve the problem in most of the cases, in addition, advances in analytical cell phone technologies are providing fair tools to meet the challenges.

28.11 SERVICE PROVIDER LOGS

Service provider's log carries a lot of useful Forensic information about a cell phone to which he provides the services. It gives the section area, keeps the account, bills the customer and its tower provides the interface. It can provide a lot of information including:

1. Calls characteristics: the number called, time, place, date, duration of the call.
2. The number of times the number was called with time and date.
3. The location of the phone.

28.12 EVIDENCE PRESENTATION

The words of an expert are no longer sacrosanct and the gospel truth. Nobody accepts the *ipse dixit* of the expert. His report, therefore, in addition to being precise, concise and intelligible must:

1. Give the referral data (FIR with dare/place, reference letter no, Report No. with date and specialist's signature, name, designation).
2. Give the gist of the work done, along with illustrations and relevant images to support the findings.
3. Mention the tools and techniques used, quote or give references to show that they are generally used and accepted by the forensics community.
4. Emphasise that the tools and techniques used are recognised and accepted for the type of work done with a known margin of error.
5. The data presented is adequate to support and prove the given conclusions and accepted by the expert fraternity.
6. Use lucid language.
7. Use data, illustration, photographs and citations to convince the court.

29.1 GENERAL

"Person authentication by voice: a need for caution."[1]

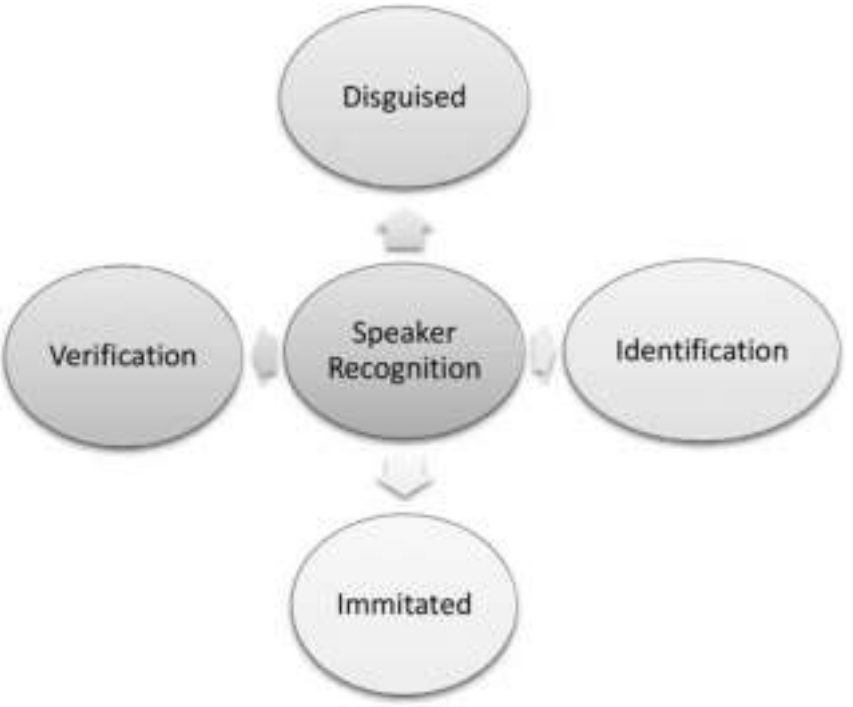

Fig. 29.1

Human beings, as well as animals, produce sound. The former can articulate the sound to produce and create a language through which they communicate with one other. The animals cannot articulate their sounds and thus are unable to create a language of their own. The capability of the human being for the articulation of the sound distinguishes him from the other species.

The voice of a person (as well as that of an animal) is unique, personal and non-imitable in its entirety because each speaker has his or her characteristic manner of speaking, including the use of a particular accent, rhythm, intonation, style, pronunciation pattern, choice of vocabulary. In addition, the structures of vocal cord, throat, and mouth vary. Under normal circumstances, therefore, the voice can permit recognition[2] of the speaker, most of the times. The voice communications were possible among the persons who were within hearing range, and they could identify each other from their voice. Most of the time, they could see each other and hence identify the speaker visually. The modes of voice communications have changed drastically in the last hundred years or so. The communicating persons need not be within the hearing range nor they need visual observations to identify the speaker, facing one another or be present within hearing range. They can be anywhere in any part of the world, in the sky or

1. 8th European Conference on speech communication and technology, Geneva, 2012.
2. Recognition includes both identification and verification of the speaker.

even under water, yet they can talk to each other. This has been possible through the extensive development in voice communication systems including the following:

1. Telephones
2. Wireless telephones
3. Satellite telephony
4. Mobile phones
5. Tape, wire and disc recording and playing the recorded version is common. The modes of recording voice (cassettes, floppies, and discs) are becoming legion and increasing.
6. Notebook, Laptop, Computer and Internet communications are the order of the day.

The criminal has seen the possibilities for misuse of the various modes of voice communications, believing that he will remain *incognito*, and thus nobody would see and identify him. It is fortunately no longer true. The voice can identify him and pin the crime on to him usually in all normal cases.

Voice identification has been practised from time immemorial. It was first used to identify the voices of birds, beasts and wild animals. In addition, the voice was and is used to identify our kith and kin as certainly and as correctly as by visual observations. The problem arises when the voice is disguised or imitated; or, it is the unfamiliar voice of a stranger or, in some cases, it is a recorded voice.

> *The misuse of an imitated voice for criminal purposes is mentioned in our sacred mythology 'Ramayana'. When Lord Rama left to hunt and catch the golden deer, goddess Sita heard her husband's voice, calling for help. Mareech, Ravana's agent, imitated the voice. Sita forced Lakshman to the scene. It facilitated abduction of Sita. (CH)*

Numerous hurdles, including the following, obstruct voice identification:

1. **Intra-speaker Variations:** There are always inter-speaker variations. Simultaneously, there are intra-speaker variations also which hinder feature selection of the voice. The normalisation of the identifying features is now routinely attempted to secure better verifications.
2. **Disguise:** The identification of birds, beasts or human beings by voice was primitive but it was quite effective. There was (is) no disguise in their voice. Humans, however, can disguise their voices. It is often difficult, if not impossible, to identify or verify the speaker when the voice is disguised. There are numerous modes of disguising the voice, including the ones given below:
   - The outgoing sound is partially obstructed; for example, covering the mouth is covered with cloth/paper
   - Mimicking the voice of others; to hide one's own voice
   - Speaking with food or other object in the mouth; the mode can be quite effective with the right object and some practice
   - Closing the nostrils; the sound characteristics change considerably
   - Adopting some dialect with a different accent
   - Using electronic voice changer (gadget)

Identification of human voice through listening still continues. Both the lay and the expert witness gives evidence on the basis of the aural evaluation of the voice. But now almost in all cases, instrumental evaluation (sound spectrography) is also produced. Instrumental methods are useful and handy but they are not infallible, as one would wish them to be.

In fact, the instrumental evaluation has now taken the central stage.

3. **Age Effect:** It is elementary that in old age the loss of teeth has adverse effect on vocal envelope; bring in subtle changes in the voice. They are taken into account in speaker identification or verification.
4. **Health Effect:** The weak health or ailments bring in changes in voice like those due to old age. Obviously, the extent of change depends upon the degree of deterioration of health.
5. **Emotional Disturbance:** Extreme fear hatred, anger, shock affects voice. Their possible influence is considered while carrying out voice analysis.
6. **Miscellaneous:** In addition to the above, background noise, recording device noise, reproduction machine noise, mimicking, and other problems also affect.

29.2 IMPORTANCE

Identification of voice or sound has always been important. It is becoming increasingly more important when voice mode of communications have adopted analogue, digital and electronic mode for recording, storage, and transmission for all types of utterances not only in social, entertainment and business matters but in communications of the criminals *inter se* and with others (victims). Consequently, voice recognition is receiving a lot of attention. The voice scientists are busy to make voice communications secure and safe and to handle the criminal through voice recognition.

In forensics context, voice recognition is important for:

1. Identification of the criminal (speaker) from their telephone and other recordings; the identification (recognition) of criminals from voice is being used increasingly and effectively to identify criminals, group of criminals, conspirators, abettors and supporters of criminals. It is also becoming a potent weapon against corrupt politicians, officials and businesspersons.
2. Verification (authentication) of the speaker
3. Criminal's profile; it is being built from the utterances of a criminal. They are assuming great importance in fixing his place of origin, his social status and his mental and emotional personality. Forensic psychologists are doing a yeoman's job in providing the profile.
4. Determination of the integrity of the utterance recorded on various mechanical, electronic devices.
5. Enhancing the intelligibility of utterance.
6. Transcription and analysis of the disputed utterance.
7. Identification of objects or persons in the tape.
8. Authentication of audio tapes.
9. Identification of pirated cassettes, VCD, DVD, MP3 CD.
10. Enhancement or improvement of tape-recorded text wholly or partially.
11. Preparing authentic duplicates for courts and other purposes.
12. **Forensic Biometric;** it is the most revolutionary development pertaining to voice recognition in recent years. Voice is being used increasingly for authentication/ identification of individuals in banking industry and in online business transactions. Speaker authentication acts as a "gatekeeper" and allows transactions only after

verification of the voice of the account holder. It detects the fake voice if a person impersonates other's voice to commit fraud. In addition, it identifies the fraudster if he happens to be on the roll of the system.

Speaker recognition is pattern recognition. Spectral patterns (features) are used in representing speaker characteristics. The various technologies used to process and store voice prints include frequency estimation, pattern matching algorithms, neural networks, matrix representation, Vector Quantization and decision trees

Ambient noise levels can impede both collections of the initial and subsequent voice samples. Noise reduction algorithms can be employed to improve accuracy, but incorrect application can have the opposite effect. Voice changes due to ageing may impact system performance over time. Some systems adapt the speaker models after each successful verification to capture such long-term changes in the voice, though there is debate regarding the overall security impact imposed by automated adaptation.

Capture of the biometric voice is seen as non-invasive. The technology traditionally uses existing microphones and voice transmission technology allowing recognition over long distances via ordinary telephones (wired or wireless). Digitally recorded audio voice identification and analogue recorded voice identification uses electronic measurements as well as critical listening skills that a forensic expert applies for the identification to be accurate.

Voice biometrics, used in the banks, meet new regulations designed to protect individuals from identity theft and requiring higher levels of authentication/ verification. For example, US banks must provide three levels of authentication/verification in all over-network transactions. These higher levels must have answer to the question,

"Is this person the same person who he/she claims to be?"

The following three parameters are used commonly to find answer to the question:

1. Something the person knows; such as, a password or PIN;
2. Something the person has; such as, a credit card or token;
3. Something the person has (such as, a fingerprint, a retinal pattern,) which is used as a biometric.

Voice biometrics is being used increasingly in banks because of convenience. It provides a three-in-one solution for safe/time/cost effective banking.

The voice has been used as important clues in many types of criminal cases.

1. *In the Bombay bomb blast case of 1993, the main perpetrator, abettors and controllers were identified through telephone tapping and recording their voices. (CH)*
2. *In cricket match fixing, Hansie Cronje, South Africa team Captain, was fixed through telephonic conversations he had with bookies. (CH)*
3. *In the murder of a press reporter, the main organiser of the murder, allegedly a senior police officer, was identified through voice identification. (CH)*
4. *In the terrorist attack on Parliament, on 13 December 2001, the main organiser, a Prof. of Delhi University was identified through mobile phone tapping and recording his voice although the mobile recording was very noisy. (CH)*
5. *In spot fixing in IPL 2013 cricket the culprit cricketers were fixed through their identification from telephone conversation. (CH)*

Voice identification often plays a decisive role in the following types of cases:

1. Ransom cases, blackmail, threats, obscene calls, extortion, political or other intimidation
2. Bomb or fire hoax

3. Black box voice identification
4. Intelligence collections — identification of spies, saboteurs
5. Identification of drug dealers — manufacturers, smugglers, suppliers, distributors, peddlers
6. Identification of smugglers, their contacts, distributors and sellers of smuggled goods in the country
7. Identifications of terrorists, their partners, paymasters, supporters, and sympathisers; through their voice identifications and thereby finding proof against them
8. It is a potent weapon against the culprits who deny corruption charges. They claim a frame up. Voice recording overcomes the frame-up story.

   In a case, still pending in the court, the conversation of chief minister of a state and his wife with the persons who allegedly offered bribe was recorded. The chief minister denied the conversation, alleging it to be a frame-up. The report of the voice scientist did not identify the voice of the chief minister and his wife in the recorded conversation. (CH)
9. Involvement of individuals in planning and execution of murders and other crimes
10. Illegal deals in money, land or property, use of black money, transfer of money abroad illegally — *Hawala* (money laundering) transactions
11. Match fixing.
12. Soliciting — proof thereof.
13. Malingering — identification of the voice of the malingerer, which is recorded covertly.
14. Identification of the persons involved in organised crime.
15. Identification of pimps

    Once one of the gang leaders in Mumbai was identified to be talking to a film star, assuring the latter that his rival would be eliminated. The telephonic conversation was recorded and the voice of the involved persons identified. (CH)

29.3 NATURE

When we expiate air energy to create noise, we cause vibrations in the vocal cord and other related organs. They generate sound (voice). The organs involved in the creation of sound are activated to do so by the brain, the controller of human actions. The nature of the sound depends upon the number of organs involved, their dimensions (size, the shape), tissue density, elasticity and positioning. Important organs that modulate the voice are:

- Mouth
- Oral track
- Oral cavity
- Trachea
- Palate
- Tongue
- Jaw
- Tooth
- Lips
- Nostril

- Nasal cavities
- Larynx
- Pharyngeal cavity
- Lungs
- Diaphragm
- Oesophagus

Environmental voice source characteristics influence; bringing up of the person, education and many other factors influence. Emotions of the speaker also influence the utterances in many ways. The sounds produced by an individual, therefore, possess individual characteristics to form unique sound vibration patterns.

Voice analysis is mainly concerned with the identification of utterances made by a person while communicating with others. The voice of each person is unique because:

1. The vocal tract and other organs involved in the creation of the sound differ from one person to another.
2. The voice source characteristics involving mental, emotional and learning process and environment also differ with each individual.

If these sound organs are moved haphazardly, meaningless noise is created. If the sound is articulated, according to a system, it creates a recognisable voice in terms of word or other meaningful sounds. The articulated sound thus forms the basis of oral communication between human beings. Coded articulated voice is language.

Language is the creation of the following two functions:

1. **Phonation:** "Phonemes", acoustic signals, are created in this process.
2. **Articulation**: Phonemes are modulated to create intelligible words.

29.3.1 Phonemes

Phonemes are audible or even non-audible vowels and consonants. They are characterised by:

- Time domain
- Spectral domain
- Time and spectral domain

Articulation of the sound to intelligible voice (including words) occurs through tongue, lips, palate, teeth and the various cavities in these organs. As these organs have different dimensions, shapes and sizes, the articulations made by different persons are different. Thus, the sounds uttered by different persons vary. The main variants are frequencies and the dynamic range.

Pitch of the human sound normally has the following ranges:

For men	= 90 to 140 Hz
For females	= 180 to 300 Hz
For children	= 300 to 600 Hz

29.3.2 Variations in Voice

The human voice varies. Variations in human beings *inter se* are called inter speaker variations. They are due to many factors, both of organic and non-organic origin. We have already seen the variations due to organ variations.

Non-organic variations are due to:

1. Learning process of speech
2. Regional variations — influence of environment, dialects
3. Social structures
4. Educational level

The human voice also varies in the same person, from time to time. The variations are called *intra* speaker variations. In fact, no person can create exactly the same voice even with his best effort under similar situations, created one after the other. These variations are due to:

1. **Emotions;** they play an important role in speech variations. It is well-established that the psychosomatic effect can bring in changes in the voice even unintentionally. For example, when a person is asking for a ransom the fear of being caught affects the voice of the person. Likewise, when a person is giving specimen utterances, his awareness that it might bring him trouble can bring in a subtle change in the voice. The voice analyst takes into account such possible variations in his evaluations.
2. Rate of utterance
3. Mode of speech
4. Disease
5. Mood of the speaker
6. The emphasis given to a word at a particular moment
7. Physical discomfort, interference
8. Intoxication due to liquor or drugs
9. Age of the person

The success or failure of recognition of a speaker depends mainly upon:

1. **Inter-speaker variations of the voice**; it should be maximal. There is no measure developed for determining variability so far.
2. **Intra-speaker variability of the voice**; it should be minimal. It has not been quantified so far. Inter-speaker variations should be considerably greater than intra-speaker variations.
3. **The extent of the listening time** of the disputed voice
4. **The quality of utterance**
5. The efficiency of the recording and re-conversion instruments
6. The repetition of words
7. The time lapse between the two utterances; it should be minimal.
8. There should be no disguise. Unfortunately, there are ways and means by which the voice can be distorted considerably to create confusion in identification. There are devices and cell phones with such devices which can create (speak) different sounds
9. The number of possible suspects should be limited.
10. The sample utterances should be recorded, as far as possible, under similar conditions to those prevailing in the recording of the voice in the crime situations, using the same set of instruments whenever possible.
11. If voice has to be transmitted the transmission channel should be same or similar.

Kersta, who initiated voice identification technique was over-enthusiastic about the individuality of voice of each person and thought the voice remains unaffected with age, loss of teeth, tonsils. Likewise, he claimed that the attempts to disguise, mimic, ventriloquism and whispering, do not affect the identification. However, the claims were bare statement, without experimental data. The voice scientists do not accept them. Extensive research has been done to counter the inevitable variations and scientists have come up with techniques to minimise their effects. They are being used increasingly in crime situations.

Voice analysis involves certain terms (Speaker identification, Speech identification. Speaker verification/authentication, speaker diarization), which cause confusion and need elucidations:

1. **Speaker verification;** it is authenticating that the utterance is from one particular person. It is frequently used in certain security installations where the regular visitors have recorded their speech (limited volume) in a computer. When the visitor wants entry to the premises, he repeats the speech. The computer compares the two speeches. If they emanate from the source, entry is allowed. If they are from different source, entry is denied.
2. **Speaker identification/recognition**; it is the identification of the utterance of a speaker, from the utterances of a number of speakers. The problem crops up in ransom/threat/blackmail calls, obscene utterances.
3. **Speech identification/recognition**; it is to understand the contents of the utterance. In speech identification the contents of the utterance which may defy understanding due to external noise or changes in the sound are made intelligible. The need for evaluation of the speech may arise in some forensics situation the contents may incriminate or exonerate a person charged with crime. It may also reveal evidence which promotes better dissemination of justice by revealing secret or otherwise unknown evidence.
4. **Speaker Diarization**; it is identifying the same speaker in two or more utterances.

Speaker recognition systems have been classified into two main categories: available:

- Text-dependent and
- Text-independent

Text Dependent; in text dependent cases the disputed voice for verification and the exemplar (control) voice have the same word content. Here, prompts, a common password or phrase can be common for various speakers. In addition, passwords, PINs or knowledge-based information is employed for the broader database.

Text Independent.—Text-independent systems have exemplar and disputed voices in different text content. The subject may not even know that his voice is being used for forensic purposes. The identification processes are more laborious but they have the advantage that they require little, if any, cooperation from the speaker. They are, therefore, more frequently used in voice recognition.

In text independent systems, both acoustics and speech analysis techniques are used.

Speaker recognition is the major Forensic problem. It has also two sub-divisions: Speaker Identification and Speaker Authentication or Speaker Verification.

In the speaker identification task, a digital voiceprint of the speech utterance from an unknown speaker is compared with the voiceprints of known speakers. The unknown speaker is identified from the matching input utterance.

In speaker verification, the speaker claims an identity. An utterance of this speaker is compared with a standard utterance of the self-claimed person. If the match is above a threshold, the identity claim is accepted.

A high threshold rejects the identity of the impostors by the system, but with some risk of false rejection of valid users. Conversely, a low threshold enables valid users to be accepted consistently, but with the risk of accepting impostors. To set the threshold at the desired level of customer rejection (false rejection) and impostor acceptance (false acceptance), data showing distributions of customer and impostor scores are necessary.

In a sense, speaker verification is a 1:1 match where one speaker's voice is matched to one template (also called a "voice print" or "voice model") whereas speaker identification is a 1: N match where the voice is compared against N templates.

In speaker identification, the speaker speaks certain specified words, which are turned into digital or analog sound data. It is compared with corresponding data from the same text, already stored in a computer. If the data match, the speaker is identified.

Speaker identification devices are often installed at entry points, in security installation premises. The computer has voice data from all the authorised members of the staff and it picks up the right one from the many and 'passes' entry of the individual.

Speaker authentication is the same thing as speaker verification refers to the verification of the given utterance *vis-à-vis* a particular individual. His recorded voice is compared on 1:1 basis. If the identifying data matches, the identity of the speaker stands verified.

29.4 OPERATIONAL PROBLEMS

The operational problems in voice identification are many and varied. They are often inherent to the system and are tackled carefully. Some of the technical problems are:

29.4.1 Telephone Utterance

Telephone utterances are usually short in the actual crime situation. The criminal is often tense and due to psychosomatic effect, the voice is not normal. Further, the criminal may —

- Intentionally modify the voice
- Mimic the voice of some person
- Disguise his/her voice

The telephone apparatus and the recording device involved also affects:

- **Defective telephone apparatus**, voice recording apparatus or transmission device; they aggravate the voice identification problems.
- **Telephone systems reduce the frequency range** to 300 to 3400 Hz to record voice after filtering the human sound. Higher or lower frequencies in the voice are not available in the utterance for evaluations. It reduces the identification parameters considerably.
- **Transmission channel distortions**/modify sound.

29.4.2 Wire Tapping

Wire-tapping is frequently utilised source for recording the voice of the criminals covertly. The recorded voice is usually free from modifications, mimicry or disguise because the criminal does not know that his voice is being recorded. Again, the usual psychosomatic effect, present in threat, ransom or obscene calls is absent. However, if the person is under the influence of alcohol or drugs or has health problems, his voice may not be normal. The voice analysis may give erroneous results when compared with a normal voice. External disturbances (outside noises) at the recording site also affect the recorded voice and create difficulties in its identification. They make the recognition of recorded voice tough but do not inhibit it.

The operational blues of recording and transmission devices, however, continue, as in case of normal telephone calls.

29.4.3 Controlled Voice

Controlled utterance for evaluation and comparison with the disputed utterance needs vigilance. The investigator takes care to:

- **Collect sample utterances at the earliest;** passage of time may bring in changes in the health of the person that affect the voice and may increase the difficulties in evaluations.
- **Use the same (or similar) equipment** recording, transmission and reproduction; the devices have a great influence on the quality of the voice.
- **Create and record the voice under same (or similar) conditions**; whenever possible.

In spite of efforts to recreate corresponding conditions, certain lacunae remain. For example, the psychosomatic effect due to tension at the time of the commission of crime cannot be simulated.

29.4.4 Transmission Channel

In telephonic utterances, bandwidth frequency is changed to 300 to 3400 Hz. The voice, of higher or lower frequencies, is not covered. Likewise, dynamic range is controlled in telephone transmissions. The dynamic range available for voice recognition is, therefore, the recorded range only.

29.4.5 Miscellaneous

Other factors that create problems in the identification and comparison of voice are external noises, transmission rate *vis-à-vis* recording rate and the malfunctioning of the various devices involved in the process. The differences in the language used in disputed and controlled samples also create problems.

29.5 VOICE COLLECTIONS

The real voice recognition forensics involves mostly recorded voice. The major voice recording modes include:

29.5.1 Mechanical Mode

Thomas Edison gave us the famous gramophone (phonograph), a shellac disc which was the first gadget used to record voice. Later the material of the disc changed to wax or tin foil disc or tin foil drum. These modes of recording are now obsolete.

Vinyl discs replaced the above mode but they have also more or less vanished from the scene.

Motion picture audio track is also a mechanical mode. It is being used in cinematography. It is not used in non-cinematic recordings.

29.5.2 Magnetic Mode

Magnetic mode for voice recording succeeded in the mechanical mode. It has been utilised in:

- Micro Cassette Recorder
- Compact Cassette Recorder
- Reel to reel recorder

- Camcorder Analog Audio Recorder
- Video Tape
- Answering Machine

These voice recording devices are common and are still available in the market.

29.5.3 Digital Mode

Electronic mode of recording voice is the 'in thing', because of its superior quality. It gives life-like reproduction. This is the preferred mode and is being used increasingly in voice forensics. The following devices are useful:

1. Digital Audio Tape Recorder (DAT)
2. Digital Computer Cassette Recorder (DCC), Computer Disc Drive
3. Audio Recorder
4. Computer using tape drive back up or USB port removable chip
5. Answering Machines
6. Semi-conductor Memory, IC (Integrated chip) memory

29.5.4 Optical Mode

CD, CD ROM, CD-1 (interactive) CD-RC (recordable, CD-RW (rewritable) DVD (Digital Versatile Disc), and Mini Disc are the common devices in this category. They perform well.

29.6 EVALUATION

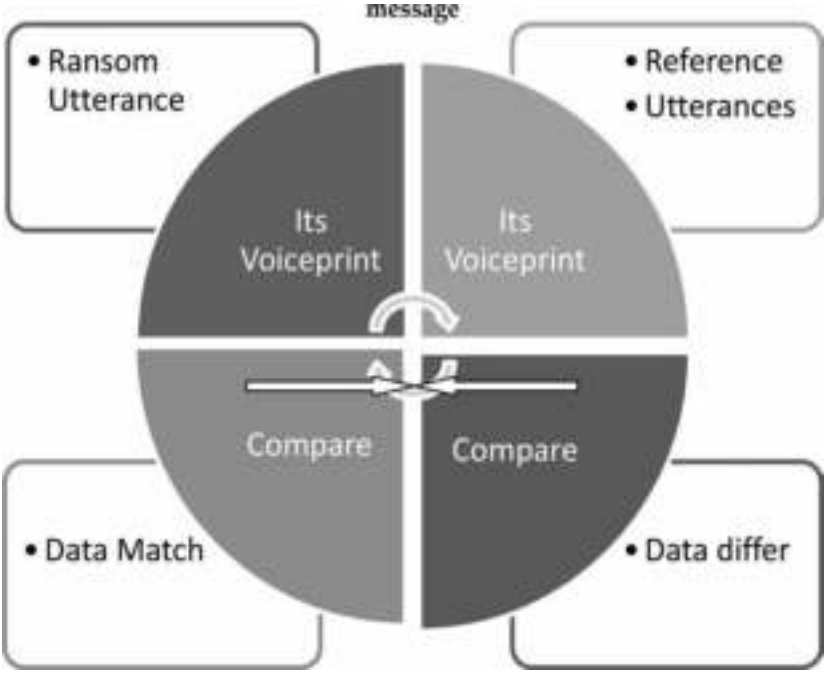

Fig. 29.2
Digital Voiceprint comparison

Voice recognition is done by three modes:

1. **S**peaker **R**ecognition through **L**istening (SLR) the voice directly or through instruments
2. Using instruments for voice collection, analysis and comparison of sound spectrogram (SRS)'
3. Combination of the two modes

In the first category, those individuals who have heard the disputed speech, as well as the specimen (ordinary), provide the evidence. The identification of the voice is highly subjective. Correct identification is possible only when the witness is familiar with the voice, and the speaker has not disguised or mimicked the voice. It is also possible if the voice of the speaker has some extraordinary identifying elements in the voice. In some cases, speech analysis (peculiar words, phrases, accent, and mannerism in talking) may help to recognise the speaker. It is rare. The factors affecting the identification of the speaker are:

- The ability of the listener for speech recognition
- The amount of utterance the person has listened to
- The familiarity with the voice
- The interval lapsed between listening to the disputed and the sample utterances. Greater the interval less reliable is the voice identification.
- The emotional conditions of the speaker, at the time of the disputed utterance, affect.
- The personal involvement of the victim creates bias.
- External noise confuses.

All of us recognise our near and dear ones through Speaker's Recognition Listening (SRL) day-in and day-out. Voice analyst also uses it extensively.

Speaker Recognition through Voice Spectrograms (SRS) are becoming more and more important as the techniques are being refined and their reliability of correct findings is increasing.

Automatic Speaker Recognition, through computers (ASR) is becoming the new tool of voice identification. There are numerous tools and techniques are being used and they are being improved continuously.

Usually, one does not depend upon one single method. Most of the laboratories doing voice identification combine the first and last techniques. Some voice analysts combine SRL and SRS.

29.6.1 Listening (SRL)

Laymen and experts both listen to the disputed and exemplar voice for recognition. Where identification of a familiar voice is concerned, the voice pattern image is already in the mind and the brain of the listener. It automatically recognises the pattern of the sound and quite correct identification is achieved in most of the cases. SRL, with an unfamiliar voice, is not so effective. However, voice analysts do acquire voice discrimination skill over time and can make fair judgments through SRL in many a case.

In crime situations, however, a familiar voice is rather rare. The nonprofessional has to identify a non-familiar voice most of the time. The expert has usually to deal with unfamiliar voices.

Listening is the first step towards voice evaluation. In some cases, it may permit the elimination of the suspect. If the pronunciation, accent, dialect, loudness or pitch differs drastically and simultaneously, there is no likelihood of possible disguise, the suspect could not be the culprit. The process of identification through listening adopted by the experts involves:

1. **Recognition of the characteristic feature**; in the voice of the suspect in the sample recorded for comparison (or in the disputed utterance). This aspect is rather difficult, as there are no known speaker specific features. The expert has to depend upon his experience to identify the characteristic features which often are:
   - Uncommon
   - Frequently occurring in the disputed utterance(s)
   - Consistent
   - Free from emotional upset or attempted disguise or imitation.
2. **Comparison**; comparison of the disputed and the sample utterances are usually subjective. The results are largely dependent upon the ability and experience of the expert. Some experts assign positions and dimensions to the various extracted features and compare the data so obtained. The approach appears to be more scientific. However, results are not much different even in competent hands.

The success or failure of aural evaluation of voice depends upon:

1. The age and sex of the speaker and the listener
2. Volume of the utterances
3. Interval between the two (the disputed and the sample) utterances.

   Experiments were conducted on the effect of time interval lapsed after listening to the voice; it was found that ability for the recognition of a voice deteriorates rapidly with the passage of time.
4. The number of persons speaking at the crime scene also affects. Experiments show a drastic decrease in voice recognition ability when the number of the person speaking is increased to five or more.
5. Absence or presence of disguise
6. Number of the speech samples
7. Influence of the recording devices
8. Environmental noises
9. The availability/non-availability of the supporting visual evidence
10. Low (< 25 dB) signal (voice) to noise ratio.

Voice recognition experts initiate voice evaluation by listening. It helps to eliminate quite a few innocent suspects without additional wastage of time and money.

Voice expert uses the following parameters to evaluate and compare the disputed and sample utterances:

1. Voice qualities: height, timbre, and fullness
2. The speech peculiarities: speech defects, if any
3. Numerous language parameters including prosody and style
4. Non-vocal speech features such as breathing patterns
5. Idiosyncrasies; abuse of certain words, phrases

6. Visual evidence (in video) of the speaker
7. If the visual evidence of the speaker is available, his mannerism helps.

29.6.2 Computer Analysis

Voice analysis has been facilitated by the advent of computers. They help to analyse, quantify and to describe precisely some of the voice identification parameters, especially:

1. Pitch and pitch contours.
2. Amplitude
3. Duration of the speech segment
4. Vibration period of the vocal cord and other sound-related organs
5. Elimination of noises
6. Efficiency of the devices used for recording, storing, transmission and reproduction of the voice.

29.6.3 Sound Spectrograph

The sound spectrograph is an instrument used to evaluate voice. It converts the speech into visual representation (voiceprints) of its frequency and intensity components. Kersta, an American, introduced the instrument in 1962. It has undergone a sea change since its induction. Kersta claimed that the spectrograms (named as voiceprints by him) obtained through the sound spectrograph were unique and individualistic in nature. He further claimed that they were permanent and remained unchanged throughout the lifetime of a person, even when the person grows old and, or loses teeth, tonsils. He stressed that even disguise or mimicry has no effect on the voiceprints. However, there was no supporting data or even a theoretical basis for these claims. He thought that the voiceprints had the same evidential value as fingerprints. A lot of research work has since been done. It has been found that none of these claims can be sustained except that they are individualistic. In fact, there are so many variables involved that it is difficult to obtain corresponding voiceprints even under ideal conditions. So far, voiceprint evidence has not proved conclusive. There are many pitfalls, which can mislead. All those who are involved in the utilisation of the evidence should be aware of the current status of the reliability of the evidence so that there is no miscarriage of justice.

Some persons have compared the voiceprint evidence to that of handwriting identification evidence. The number of variables involved therein is equally large. Further, handwriting is also amenable to disguise and forgery. Still more, it suffers deterioration due to disease, old age, injury and influence of intoxication. However, there have been a lot of inputs in the case of handwriting evaluation, and it has achieved a high degree of reliability. Similar extensive inputs are needed before the voiceprint identification can achieve a reasonably high degree of reliability. This has to be achieved because, in spite of its lacunae or pitfalls, the evidence of this type is becoming increasingly important. If voice identification does not provide positive proof by itself, it can certainly provide corroboration, indicate leads and help investigations in other ways. It is doing so in many ways.

A sound spectrograph has four parts:

1. Magnetic Recorder
2. Electronic Filters
3. A rotating drum carrying paper around, on which the spectrogram is recorded.
4. An electrically operated stylus to record the graph

The sound spectrograph analyses require only a limited amount of utterance at a time, which could be recorded in one revolution of the drum. It converts the speech signal into a visual spectrum in the form of traces of the graph. The dimensions and the intensity of the traces are dependent upon the utterance being analysed. The use of computers in conjunction with the spectrograph has increased the volume of the recordings. A personal computer based instrument, named Computerised Speech Lab (CSL) has also come up. It records, edits and quickly analyses the speech signals. It is possible to carry out the detailed studies of the utterances through segmentation of the recordings, taking one segment at a time.

When the voice of a person is subjected to spectrographic analysis, the sound energy is converted into electrical energy, which operates the stylus and the stylus, in turn, creates a trace in the form of a graph on the paper on the drum. The graph is known as a spectrogram or a voiceprint.

The spectrogram has the following elements:

1. Horizontal Dimensions
2. Vertical Dimensions
3. Shade Intensity of the trace

Horizontal dimensions represent the time interval of the speech signal. The vertical dimensions indicate the frequency and the darkness indicates the intensity of the loudness of the voice. The visual display of the disputed and the sample utterances (of the same word/text) are compared visually. The patterns have to be different for different persons, but unfortunately, they are also different somewhat for the same person. Besides, the external noises make the problems worse. Further, family members have some commonality in voice. It is due to these factors that chances of misinterpretation exist. Besides, the resolution of the spectrogram was limited previously. It has been improved in recent times and will doubtless improve the evaluations. The inadequate resolution, overlapping of voice spectrograms of the same word, even from different persons, especially from kith and kin creates confusion some times.

The process of using the method is simple. The suspect(s) is made to utter a relevant word(s) and the voice is recorded on a device similar to the one used in recording the disputed utterance. The recorded voices are then turned into voiceprints (spectrograms), their visual equivalents through the Sound Spectrograph. The spectrograms are evaluated and compared *inter se*.

29.6.4 Automated Speaker Recognition (ASR)

The Automatic Speaker Recognition (ASR) system involves the following:

1. Feature Extraction
2. Feature Comparison
3. Normalisation

29.6.4.1 Feature Extraction

Feature extraction is the most difficult task. The feature has to be unique, consistent and free from internal and external influences. It should be easily measurable, not changed with time or health of the speaker and not affected by external noise or transposing equipment. The source of the feature, the word, should be occurring frequently in the speech to make it easily available for analysis. It should withstand disguise or mimicry and it should survive the use of various machines, which are used in voice analysis. A lot of work has been done in this direction. A number of systems have been developed but none has so far given 100% reliable results. The research goes on.

29.6.4.2 Feature Comparison

As no speaker-specific features have been discovered so far, all available features are considered for comparison. The following features have been compared through computers.

1. Linear Prediction Coefficients
2. Central Coefficients

These features are evaluated and compared *vis-à-vis* similarities found on the disputed and the test speech templates by a number of systems. The Gaussian Mixture Model is found better than others. If the similarities reach the threshold[3] or go beyond, the voice is identified. If the threshold in not reached, the voice is not identified.

29.6.4.3 Normalisation

The normalisation process involves elimination or reduction of the inherent variations present in *intra* speaker utterances of the same text, the influence of environment and of the devices used in the process of identification. The following processes are used for the purpose:

1. Spectral Equalisation
2. Spectral Subtraction
3. Missing Feature Compensation

The details of these processes are beyond the scope of the present work. It may, however, be mentioned that complete success to normalise the utterances for forensic evaluations is yet to be achieved.

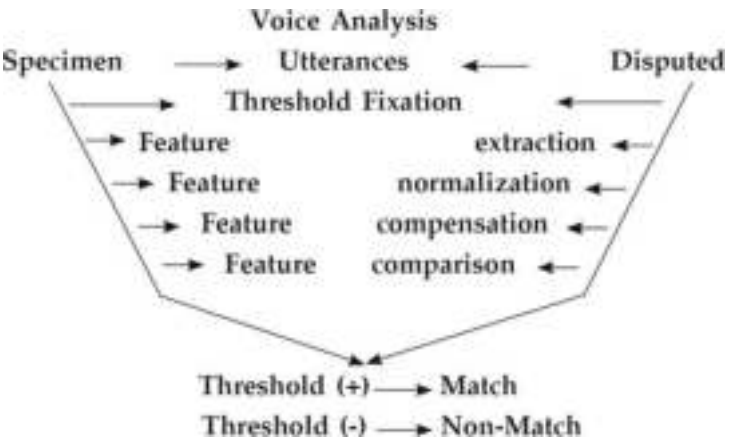

Fig. 29.3

Speaker Recognition

29.7 INTERPRETATION

All forensic identifications aim at achieving the practical individuality of the source. It is possible in some types of evidence, not in others. In voice evaluations, instrumental individualisation of voice source is difficult to achieve with certainty. It has been possible in some cases to give a high probability of the identity of the speaker. In some other cases, however, fairly high probability on the non-identity of the speaker has been achieved.

3. Threshold is the prefixed identification data for recognition of the voice.

The usual results given by the experts fall in the following categories:

1. Identification of the voice:
   - High probability
   - Probable
   - Possible
   - Evidence insufficient for opinion
2. Elimination of the speaker:
   - Positive in some cases
   - Highly probable exclusion in some other cases
   - Probable exclusion
   - Possible exclusion
   - Insufficient evidence for exclusion

29.8 MISCELLANEOUS

The evaluation of utterances is useful for many forensic needs, notably for:

1. Psycholinguistic Profiling
2. Determining the integrity of the recorded utterances
3. Transcription of the taped utterances

29.8.1 Psycho-linguistic Profiling

The personality profile of a person is built up from his utterances. The following factors help:

1. The dialect of the utterance
2. The accent of the speaker
3. The pitch and loudness of the voice
4. The words, phrases and the sentences he uses in his utterances
5. The pronunciation of the speaker
6. The defects in the voice, speech of the speaker
7. The inter-mixing of the languages, dialects, in the utterance
8. The abuse of certain words and phrases
9. The obscenities uttered by the speaker. Foul language is common among criminals
10. The pet words, slangs and phrases
11. The points or words on which the emphasis laid, in the utterances

Profiling of the criminals from language has come up as an important branch of Forensic Psychology. It is assuming greater and greater importance with the passage of time. In the absence of eyewitnesses, psycholinguistic profiling will be of great help to locate and identify a criminal.

29.8.2 Integrity of Recorded Voice

Integrity of the voice on various recording devices sometimes assumes importance, especially in the following situations:

1. Involvement of the speaker in crimes like murders, dacoities, corruption cases, organised crimes, extortion

2. Fixing adultery in divorce cases
3. Identification of members of the gang or criminal organisations
4. Identification of the fanatic speaker who inflames communal hatred or anti-national feelings/activities

29.8.3 Tampered Integrity of the Recorded Voice

There are a number of ways in which the recorded utterances are tampered. The main modes are:

1. **Deletion**; it is the easiest form of damaging the integrity of the recorded voice.
2. **Addition**; it is also easily done
3. **A synthesis of utterances**; from some innocent recorded speech/ utterance/ conversation

The alteration of a recorded voice can be accomplished on all sorts of recording devices. It is comparatively easier to make changes in digitally recorded speech than that on a magnetic tape analog.

It is often difficult to know the deleted text though it may be possible to detect alteration. The success or failure of the detection depends upon the extent of the alterations made. Lesser the volume of the altered text, fewer is the chances of detection and *vice versa.* It also depends upon the device used for making the changes. If the alteration is with the same device as used for the original input, the task of detection is more difficult. Above all, it depends upon the technical know-how of the perpetrator, the more conversant he is with the process, he does a better job of alteration, increasing thereby the difficulties of the detection and hence of the investigations.

29.8.4 Transcription

Transcription is the conversion of the recorded utterances into a written record. The process offers no problems when the person carrying out the transcription knows the language and the text is normal: not encrypted or distorted, intentionally or otherwise. In the latter cases, the evaluation of the voice may need expertise in phonetics, linguistics. Besides, in cases of gross distortions of the recorded voice one may have to use frequency filters and other devices to figure out the text. The general process of evaluation is to:

1. Listen to the entire text repeatedly.
2. Separate intelligible and unintelligible texts.
3. Separate the utterances of each person if there is more than one speaker.
4. Use sound filters to reduce/ eliminate noise and thus enhance the intelligibility.
5. Break the difficult passages into segments and subject them to phonetic, linguistic and/or spectrographic analysis, with the help of the specialist(s).
6. Demarcation of the boundaries in the spectrograms often helps.

It is not always possible to figure out the entire text of the utterance. The person carrying out the transcription should indicate:

1. The clearly identified text
2. The ambiguous text with their ambiguities
3. The possible text
4. The uncertain text

Voice analysis has been, and is, a potent weapon in the fight against crime. It has to be improved through research. This weapon will be needed more frequently in the coming times when the other types of evidence will be becoming scarcer.

Forensic phoneticians

Forensic phoneticians are like medical doctors giving prognoses. They make many tests that provide useful clues, but their opinions are inevitably based on their own experience....they have evidential value, but they are not established scientific truths[1]

Voice Disguise

If you fancy scaring the hell out of someone, while remaining totally disguised, then this is the gadget for you.

It has six voice changing options, and digitally changes your voice frequency to enable your voice remains incognito. The fun possibilities are endless. The facility is available in some cell phones.

29.10 CASE LAW

29.10.1 Tape Recorded Evidence[4]

This court in *N. Sri Rama Reddy v V.V. Giri*[5], accepted conversation or dialogue recorded on a tape recording machine as admissible evidence. In *Nagree's* case the conversation was between Nagree and Sheikh. Nagree was accused of offering a bribe to Sheikh.

In the *Presidential Election* case[6], questions were put to a witness Jagat Narain that he had tried to dissuade the petitioner from filing an election petition. The witness denied those suggestions. The election petitioner had recorded on tape the conversation that had taken place between the witness and the petitioner. Objection was taken to admissibility of tape recorded conversation. The court admitted the tape recorded conversation. In the *Presidential Election*[7] case, (supra) the denial of the witness was being controverted, challenged and confronted with his earlier statement. Under section 146 of the Evidence Act questions might be put to the witness to test the veracity of the witness. Again under section 153 of the Evidence Act a witness might be contradicted when he denied any question tending to impeach his impartiality. This is because the previous statement is furnished by the tape recorded conversation. The tape itself becomes the primary and direct evidence of what has been said and recorded.

Tape recorded conversation is admissible provided first the conversation is relevant to the matters in issue; secondly, there is identification of the voice; and, thirdly, the accuracy of the tape recorded conversation is proved by eliminating the possibility of erasing the tape-record. A contemporaneous tape-record of a relevant conversation is a relevant fact and is admissible under section 8 of the Evidence Act. It is *res gestae.* It is also comparable to a photograph of relevant incident. The tape recorded conversation is therefore a relevant fact and is admissible under section 7 of the Evidence Act. The conversation between Dr. Motwani and the appellant in the present case is relevant to the matter in issue. There is no dispute about the identification of the voices. There is no controversy about any portion of the conversation being erased or mutilated. The appellant was given full opportunity to test the genuineness of the tape recorded conversation. The tape recorded conversation is admissible in evidence.

It was said by counsel for the appellant that the tape recorded conversation was obtained by illegal means. The illegality was said to be in contravention of section 25 of the Indian Telegraph Act. There is warrant for proposition that even if evidence is illegally obtained it is admissible. Over a century ago it was said in an English case where a constable searched the appellant illegally and found a quantity of offending article in his pocket that it would be a dangerous obstacle to the administration of justice if it were held, because evidence was obtained by illegal means, it could not be used against a party charged with an offence. See *Jones v Owen.*[8] The Judicial Committee in *Kuruma, Son of Kanju v R.*[9] dealt with the conviction of an accused of being in unlawful possession of ammunition which had been discovered in consequence of a search of his person by a police officer below the rank of those who were permitted to make such searches. The Judicial Committee held that the evidence was rightly admitted. The reason given was that if evidence was admissible it matters not how it was obtained. There is of course always a word of caution. It is that the judge has a discretion to disallow evidence in a criminal case if the strict rules of admissibility would operate unfairly against the accused. That caution is the golden rule in criminal jurisprudence.[10]

2. It is too late in the day to challenge the admissibility of a conversation which has been tape-recorded earlier if the same is relevant. As early as 1956, Bhandari, C.J. in *Rup Chand v Mahabir Parshad*[11] had categorically laid down that such a tape-recording was clearly admissible. The learned Chief Justice had relied on a number of American and English cases in support of his decision. In *S. Partap Singh v State of Punjab,*[12] the learned judges of the Supreme Court relied heavily on the tape-recording which had been put on the record by the petitioner. In fact the admissibility of the same was considered self-evidence. Their lordships expressly

adverted to the admissibility and the evidentiary value of the tape-recorded talk which had been produced as part of the supporting evidence produced by Dr. Partap Singh, the petitioner in that case. A clear and unequivocal enunciation of the law is made, however, by the court of Criminal Appeal in *Rex v Maqsud Ali and Ashiq Hussain,*[13] in the following terms:

> *We think that the time has come when this court should state its views of the law on a matter which is likely to be increasingly raised as time passes. For many years now photographs have been admissible in evidence on proof that they are relevant to the issues involved in the case and that the prints as seen represent situations that have been reproduced by means of mechanical and chemical devices. Evidence of things seen through telescopes or binoculars which otherwise could not be picked up by the naked eye have been admitted and now there are devices for picking up, transmitting, and recording conversations. We can see no difference in principle between a tape recording and a photograph. In saying this we must not be taken as saying that such recordings are admissible whatever the circumstances, but it does appear to this court wrong to deny to the law of evidence advantages to be gained by new techniques and new devices, provided the accuracy of the recording can be proved and the voices recorded properly identified; provided also that the evidence is relevant and otherwise admissible, we are satisfied that a tape-recording is admissible in evidence. Such evidence should be regarded with some caution and assessed in the light of all the circumstances of each case. There can be no question of laying down any exhaustive set of rules by which the admissibility of such evidence should be judged.*

Lastly in *Yusufalli Esmail Nagree v State of Maharashtra,*[14] the learned judges of the Supreme Court in expressly considering this case have observed as follows:

> *The process of tape-recording offers an accurate method of storing and later reproducing sounds. The imprint on the magnetic tape is the affect effect of their relevant incident, a contemporaneous tape-record of a relevant conversation is a relevant fact and is admissible under section 7 of the Indian Evidence Act.*

Their lordships in this case noticed the reasoning of *Rup Chand's* case[15] with approval. In this context it is futile now to argue that a tape-recording is not admissible in evidence.

Once it is held that a tape-recording is admissible, the manner and mode of its proof and the use thereof in a trial is a matter of detail. That it can be used for the purpose of confronting a witness with his earlier tape-recorded statements admits hardly of any doubt. That it may also be legitimately used for the purpose of shaking the credit of a witness was laid down in clear terms by Bhandari, C.J., in *Rup Chand's* case[16] in the following terms:—

> *I am aware of no rule of evidence which prevents a defendant who is endeavouring to shake the credit of a witness by proof of former inconsistent statements from deposing that while he was engaged in conversation with the witness a tape-recorder was in operation, or from producing the said tape-recorder in support of the assertion that a certain statement was made in his presence.*

That being so, for a use of an earlier tape-recorded statement, the identification of the taped voices is hence a crucial matter and indeed such proper identification is the *sine qua non* for the use of the earlier tape-recording. The relevant authorities are all unanimous on the necessity of such proper identification of the taped voices. In *Yusufalli Esmail Nagree v State of Maharashtra,*[17] it was observed as follows:

> *If a statement is relevant an accurate tape-record of the statement is also relevant and admissible. The time and place and accuracy of the recording must be proved by a competent witness and the voices must be properly identified.*

The cases where the taped voice is admitted thus present no difficulty. However, where the voice is denied by the alleged maker thereof, a comparison of the same becomes inevitable. As observed by the Supreme Court the proper identification must be proved by a competent witness. Learned counsel has been unable to point out anything in the relevant statute which

13. (1965) 2 All ER 461 (464).
14. AIR 1968 SC 147 : 70 Bom LR 76 : 1968 Mad LJ (Cri) 247.
15. AIR 1956 P&H 173 : 58 Punj LR 441 : ILR 1956 Punj 1351.
16. *Ibid.*
17. AIR 1968 SC 147 : 70 Bom LR 76 : 1968 Mad LJ (Cri) 247.

expressly or impliedly may tend to prohibit such a comparison. At the present stage the nature of the evidence that would be brought forward for this purpose, and whether the court can itself compare the admitted and the disputed tape-recording is not yet in issue. I am, therefore, inclined to the view that the orders of the courts below are thus clearly sustainable.[18]

We are left with the tape-recorded conversation which according to the prosecution, corroborates the evidence of P.W. 1. A tape recorder was given to P.W. 1 to record the conversation. The learned Magistrate while dealing with the recorded conversation on the tape states:

> I closely observed the playing of the cassette in court and found that it contained substantially the version given by P.W. 1 in court regarding the conversation had by him at the time of alleged payment of amount to him.

I may at once point out that I have also had the tape M.O. 3 played in open court and to me most of the conversation was not clear. Even P.W. 1 is of the same view. He states that certain portions in the tape are clear and other portions are not clear. He also states that he does not know the reason for that. P.W. 3 states that the tape recorder was played in the office in the presence of the appellant and others and it contained the conversation between P.W. 1 and the appellant. He would also say that M.O. 3 was played again in the office at 3.40 p.m. and a transcript of the dialogue between P.W. 1 and the appellant was taken in his presence and that is Ex. p 13 in which P.W. 8 and the three inspectors have attested. In cross examination he admitted that when for the first time tape recorder was played, the entire conversation was not transcribed and therefore it was played again and certain portions in the conversation are not clear. P.W. 8, the investigating officer, admitted that he heard the tape recorded conversation and in some places the conversation is not quite clear. P.W. 8 is not able to say as to who spoke the words 'Please don't take it as a bribe'. In *Yusufalli Esmail Nagree v State of Maharashtra,* AIR 1968 SC 147 : 70 Bom LR 76 : 1968 Mad LJ (Cri) 247, the Supreme Court observed:

> *If a statement is relevant, an accurate tape record of the statement is also relevant and admissible. The time and place and accuracy of the recording must be proved by a competent witness and the voice must be properly identified. One of the features of the magnetic tape recording is the ability to erase and re-use the recording medium. Because of this facility of erasure and re-use, the evidence must be received with caution. The court must be satisfied beyond reasonable doubt that the record has not been tampered with.*

Bearing these observations in mind, we may analyse the evidence in regard to the tape recorded conversation. I earlier pointed out that P.W. 1, P.W. 3 and P.W. 8 say that certain portions of the conversations between P.W. 1 and the appellant recorded by the tape-recorder are not clear. The evidence of P.W. 3 also shows that the tape-recorder was played twice. The most important condition of identifying the voice has not been satisfied in this case. P.W. 8, the investigation officer, admits that he did not examine P.W. 1 with reference to the conversation in the tape. P.W. 1 states in his evidence that he heard the tape-recorded conversation for the first time in court (before the trial magistrate). The evidence of P.W. 1 and P.W. 8 very clearly shows that the voices of P.W. 1 and the appellant have not been identified. Without identifying the voice Ex. p 13, which is a transcript of the alleged dialogue between P.W. 1 and the appellant was prepared by P.W. 8, the investigating officer. It is not clear as to how in the transcript Ex. 13, P.W. 8 is able to point out the words spoken by P.W. 1 and the appellant. Even in the transcript, we find a reference to the fact that the conversation is broken at a very crucial place. The appellant in his statement states that the conversation has been tampered with. P.W. 1 should have identified his voice and the voice of the appellant in the recorded conversation. But P.W. 8 admits that the tape was never played before P.W. 1. P.W. 1 himself says that he heard tape-recorded conversation for the first time in court. The accuracy of recording has not been proved by a competent witness and the voices have not been properly identified. Under those circumstances it is not safe to rely on this tape-recorded evidence of P.W.

30.1 GENERAL

Forensic psychology is the body of the scientific knowledge of psychology, applied and utilised in legal matters, usually in the court of law. It may be used at the pre-trial stage, during the trial or at post-trial stage. The American Board of Forensic Psychology has defined forensic psychology in the following words:

> *Forensic Psychology shall mean the application of the science and profession of psychology in relation to questions and issues to law and legal systems.*

A more comprehensive definition includes its diverse involvements and applications. Thus:

> *Forensic Psychology is the development and application of the principles of psychology to solving and the handling of legal, judicial, correctional and law enforcement problems which have their roots in psychology and its branches. It is multidisciplinary in nature and involves both social sciences (law, Sociology, Political Science) and natural sciences (Anthropology, Medicine.).*[1]

Forensic Psychologist is one who has studied psychology, who is trained in Forensic psychology and who practises it in court as an expert to assist the courts to assess the personalities of the persons involved and to evaluate the occurrences accordingly.

1. Adapted from the definition given in JJ College Website.

Forensic psychologists work for both prosecution and defence and of course, assist the courts in evaluating persons, events and situations.

The terms "Forensic Psychology" and "Forensic Psychiatry" are often used interchangeably. They are two distinct disciplines. Forensic psychiatry deals with medical problems relating to mental abnormality. The psychiatrist is sometimes called to give evidence whether the accused person, who has taken insanity as a defence, is really insane or he is shamming insanity. In some cases, a man with mental abnormality may have committed a crime. The psychiatrist assesses if criminal responsibility can be attributed to that person. The psychiatrist in such cases has to appear in courts. Hence, the terms: Forensic Psychiatry and Forensic Psychiatrist.

Forensic psychology/psychologist is not involved in the medical mental aberrations problems. They are concerned with the behaviour, thought processes and the intentions of the persons involved and also their effects on the body — the psychosomatic manifestations. In some cases, a forensic psychologist is also called to assess mental abnormality but in such cases, a psychiatrist should also be consulted. Ordinarily, the Forensic Psychiatrist has his basic education in medicine, and the Forensic Psychologist has his basic education in psychology.

30.2 NATURE

Forensic psychology, as already seen, is the application of psychology in the dissemination of justice. Psychology in itself means the study of human behaviour, a person's thought processes, his intentions, his attitudes toward humans, towards life, his concepts of right and wrong and his thinking about his duties towards the society and *vice versa*. The major problem in Forensic psychology is to understand the above traits of human behaviour and to link or de-link them with the criminal act. The second important task of Forensic psychology is to rehabilitate the convicted offender. In addition, forensic psychology also tackles many other forensic problems. They are enumerated below.

30.2.1 Emotions

The investigators, the counsels and the judges have been utilising forensic psychology even in olden days but without a name. Ordinarily, stress and conflict created emotional upset under certain situations. For example, when a person is being interrogated about an unpleasant matter, his emotions about the matter would be reflected in the form of body signs: Psychosomatic manifestations! Varied emotions create these body signs. In general, they are due to:

1. Fear
2. Anger
3. Greed
4. Ego
5. Love/hate
6. Fanaticism/religious fervour
7. Sense of duty — towards family, community, society, nation, humanity
8. Happiness
9. Courage
10. Human values
11. Disgust, sadness
12. Compassion

30.2.2 Body Signs

The subject manifests body signs, under both u-stress and distress. They include:

1. **Facial Changes:** if the subject is frightened, his face would turn ashen. If he becomes angry, his face would redden. "Lost colour" and "red faced" are the phrases often used in such cases, respectively.
2. **Contortion:** the subject, under great mental stress and conflict, suffers facial contortions. Lips, nose, cheeks, forehead often distort. Eyes may start watering (weeping), or they may become "bloodshot".
3. **Perspiration:** the subject perspires when frightened.
4. **Stuttering:** the subject stutters if he is asked incriminating/embarrassing questions.
5. **Eye contact**: the subject avoids eye contact. He shifts eyes under stress/fright.
6. **Fidgeting:** the subject shifts his body position frequently when he finds the interrogation uncomfortable. He may also scratch some body parts.
7. **Dry Mouth:** the subject takes frequent sips of water, as fear turns his mouth dry.
8. **Delayed answers:** the subject takes a longer time to answer questions or stops answering questions altogether when he wants to avoid answering or to tell lies.
9. **Emotional breakdown:** the subject may break down and start weeping.
10. **Hysterical fit:** the subject goes hysterical and starts abusing, quarrelling or laughing. He may even try to harm himself or the interrogator.

30.2.3 Subtle Psychosomatic Changes

In addition to the visible body signs, the subject under stress also suffers invisible subtle psychosomatic changes. Instruments have come up to detect these changes. They are being used in interrogations to find the truth. The changes utilised are in:

- Blood pressure
- Respiration rate
- Pulse rate
- Electrical resistance of the skin
- Subsonic vibrations of the vocal cord
- Brain activity: Brain Electrical Activation Profile (BEAP)

Numerous tools and techniques are utilised to study these changes extensively in interrogation. The important ones, which are becoming more and more popular, useful and assuming tremendous importance, are:

1. **Psychological Detection of Deception (PDD):** Polygraph — A Lie Detector is the instrument being used for the purpose.
2. **Narco-analysis:** it is an interrogation technique. It was not exploited extensively in the past. It is being used increasingly now. It involves the brain part, which invents false answers through its reasoning. Narco-analysis suppresses its reasoning and rationalisation power and the subject give truthful answers.
3. **Brain printing or profiling:** it is believed that brain profiling has a great future to extract the truth. The brain is the storehouse of all information that a person possesses. If this source can be tapped to get the truth, it can be an immeasurable

help to the criminal justice system. Tremendous research work is going on just trying to find ways and means to get at the truth via brain printing.

4. **Hypnosis: it** means putting the subject in a trance and interrogated. In this state of trance, the subject is not able to reason. He, therefore, speaks whatever he remembers of the occurrence. Hypnosis has proved useful in many cases especially with frightened subjects.
5. **Psychological Stress Evaluator:** it utilises sub-sonic vocal cord vibrations which show changes when the person is telling lies. The voice and vibrations are recorded, and the sub-sonic vibrations are studied. It can be used both overtly and covertly.

The method has not been used extensively in crime cases.

30.3 APPLICATIONS

Forensic psychology is comparatively a newcomer in the criminal justice system in India. However, due to its wide and impressive applications, its use is increasing rapidly in all types of cases involving criminal, civil, family and juvenile laws. Its use prevails in all aspects of criminal justice system: at the investigative stage, in trials, to ascertain if the subject is fit to undergo a trial or capable of giving evidence, in determining quantum and nature of punishment or at the correctional stage to guide the juveniles. In addition, it tackles social deviance among the prisoners.

Forensic psychology, in brief, helps to ascertain:

1. **Sanity:** is the accused person sane, capable of understanding the nature of the crime and that of trial. Or, is he insane and does not understand the nature and the meaning of crime and the proceedings, and thus incapable to plead his case, or to waive his right to defend himself.
2. **Malingering:** is the person feigning incapacitation to claim damages in some case of an accident in which he was involved? Or, is he exaggerating the incapacitation?
3. **Treatment of juvenile offenders:** forensic psychologists are being used increasingly to treat juvenile offenders to bring them to normal behaviour, often on the recommendation of the juvenile courts.
4. **Accused adult or juvenile:** a forensic psychologist can evaluate and help the court to decide whether the person undergoing trial should be treated as an adult or as a juvenile, as per his mental and emotional development, at the time of committing the crime, or at the time of trial.
5. **Nature and quantum of punishment:** a forensic psychologist can help the court to decide about the quantum of punishment to meet the ends of justice on the one hand and the welfare of the society on the other. What should be the best punishment in a given case? The court often has to decide whether the person under trial should be sent on probation; or, should he be sent to prison. Psychological evaluation helps to decide.
6. **Delinquent's personality assessment:** juvenile courts often need a brief on the personality of the delinquent so that they can choose the correct sentence — alternative to imprisonment: probation, or psychotherapy, to make him a useful citizen without endangering the society. The forensic psychologist, after evaluation provides the brief.
7. **Competency of the subject:** courts and public are increasingly demanding determination of competency of a person for:
   - Guardianship of a ward

- Awarding citizenship to an immigrant applicant
- Making a Will, Contract, and Conveyance Deed
- Suitability of a person as a marriage partner
- Suitability for employment, especially in sensitive secret government organisations
- Admission to prestigious institutions
- Degree of impairment or disability for compensation assessment
- Placement or promotions

8. **Criminal's profile:** profiling of the criminal, for court purposes, is extensively being utilised from the following:
   - Psycho-linguistic analysis
   - Behaviour at the crime scene
   - Treatment of the victim(s)
   - Vandalism at the scene
9. **Prediction of violence and assessment of risk:** the post-conviction treatment of the criminal depends upon whether the criminal is prone to violence and if so how much is the risk. Forensic psychologist is the person to determine it.
10. **Criminal responsibility:** the criminal responsibility of a person involved in a crime varies. .Was he provoked? Was he taking revenged? Or, did he commit the crime for sadistic pleasure? Forensic psychologist is a person to determine it.
11. **Mitigating factors:** the psychologist ascertains if there were some mitigating circumstances which should invite lesser punishment to the accused.
12. **Drug addiction:** the science is being used to ascertain whether the given person is a drug addict or has a tendency to become one.
13. **De-addiction:** forensic psychologist is helping addicts and drunkards to bring them to normalcy.
14. **Truth through interrogation:** most importantly, Forensic psychology is being utilised in the interrogations of the culprits (suspects), victims and witnesses for finding out the truth about the occurrence and background information about the crime.
15. **Stress management:** Forensic psychologists are helping criminal and shocked victims of crime to normalisation by stress management.

Forensic psychologists are increasingly participating in the teaching and training program of the investigating officers, prosecutors and judges so the justice delivery system is improved.

16. Dissemination of essentials of Forensic Psychology to non-expert professionals (judges Lawyers, Reformatory home and prison staff).

30.4 CLASSIFICATION

Forensic psychology is usually divided into the following classes for the convenience of study and application:

1. Clinical Psychology
2. Experimental Psychology
3. Statistical Psychology

4. Psycho-therapy
5. Consultancy Psychology

30.4.1 Clinical Forensic Psychology

The clinical approach evaluates the subject in its entirety: environmental influence, educational contributions, marital influence and family background. Complete understanding of the subject facilitates better handling of the problems of the subject.

Clinical forensic psychology requires a close personal relationship of the forensic psychologist with the subject for better evaluation of the subject in all aspects. In short, it is a subject-centered process. The clinical approach often develops into a personal relationship, which may raise some ethical problems sometimes.

> *In a case of killing of an intruder, the husband claimed that he killed the intruder because the fellow had assaulted his wife. The wife claimed that her husband was not at home and the intruder had entered the house and did not leave the house in spite of her warning him a number of times. As he threatened to overpower her, she, in self-defence shot at him and killed him. The court called in a forensic psychologist to resolve the issue. It appeared that the husband was not present at the scene at the time of occurrence. The case was adjudged as a case of killing in self-defence. It ended in acquittal. (CH)*

The maximum use of clinical psychology is in road accident cases where damages are claimed for possibly non-existing injuries or trauma. Clinical psychology has also assisted to unravel the allegedly false rape cases.

> *A young lady approached the police that someone was pestering her through obscene calls. The police checked all the incoming calls for a number of days but there were no such calls. When she persisted in her complaints, a psychologist was asked to check her. He that there were no such calls. She was told accordingly and asked to stop pestering the police. (CH)*

Rash drivers, being prosecuted, sometimes seek the help of a forensic psychologist to establish mitigating circumstances for the cause of the accident.

Clinical forensic psychology has also proved useful in cases of nervous victims or witnesses. Hypnosis has been successfully employed in some cases.

> *A sex criminal attacked two girls. The girls offered resistance. In the fight he killed one of the girls and raped the other. The girl was so frightened that when the police would start interviewing her about the assailant she would swoon. Ultimately, she was put under hypnosis for interrogation. The girl not only gave a complete description of the culprit but also informed the police that she had seen him, more than once, before the occurrence also. The police was sure that the culprit was a local person. They also reconstructed the photograph (photo-fit method). When the girl was shown the photograph she swooned again, confirming thereby his identity. (CH)*

30.4.2 Experimental Forensic Psychology

Experimental forensic psychology has become a convenient handmaiden of the criminal justice system. It can analyse, explain and predict facts in such definite terms in some cases that it is simply amazing. It is helpful to solve many legal problems of diverse nature whether they are criminal or civil in nature. The following situations illustrate the use of experimental psychology to serve the cause of justice:

> *In a case of an accident due to rash driving, it was essential to check the truthfulness of a person who gave the evidence that he could read the registration number of the offending vehicle. The witness was asked to note the number of a running vehicle at a particular speed from the distance given by the witness, under the lighting conditions of the incident at the spot where the accident had occurred. He could not read the number. (CH)*

Whether a plea for diminished responsibility can be accepted for a given reason beyond the control of the accused person can also be ascertained by experimental psychology.

In a case, the accused alleged that the accident has been caused because he had taken some medicine. The accused was given the same dose of medicine, which had caused the accident without his knowledge. The person was observed to see if the drug has adversely affected his faculties and thus could have caused the incident. The medicine did not affect the accused. (CH)

Experimental data may be needed in certain claim cases to ascertain the validity or otherwise of the claim.

In a case of death of a worker due to an accident in the factory, the management claimed that the accident was due to negligence of the worker. The relatives of the worker, on the other hand, claimed a lack of adequate safety measures. Previous records were checked. New experimental data was generated. It was found that the machines did need additional safety measures. The management had to pay appropriate compensation. (CH)

Ordinarily, the experimental work is conducted at the site of the incident, simulating the conditions of the incident. However, sometimes the experiments have to conduct in the laboratory or where the subject is housed, including the jail rooms or at the premises of the jail. As long as the subject and the authorities are willing to cooperate, the site of the experiments poses no serious problems in most of the cases.

Experimental forensic psychology has been extensively utilised to establish *corpus delicti* and the identity of the culprit.

30.4.3 Statistical Forensic Psychology

Evaluations of statistical data of forensic importance relating to forensic psychological studies of a subject have always been important and have been utilised extensively over the years. The main sources for the data are:

1. The personal history of the subject in its entirety, especially relating to psychological aspects, is important. The data is obtained from the members of the family, friends of the subject, his schoolmates, schoolteachers and colleagues. If he is a member of a club, the staff and the members of the club may also be in a position to provide necessary data.
2. Writings and spoken words often provide useful data about the personality of the writer or speaker. Some research workers have refined the technique to a degree that they are able to indicate the personality of the subject from these studies alone. The branch of the science has been named as Psycholinguistics.
3. Interviews and interrogations are the mainstay of statistical data. It is more reliable also, as the scientist himself is collecting it. Tools and techniques of interrogation are legions.

Experimental data in some cases is indispensable to generate adequate statistical database. It must be understood that statistical data has been misused in the past. It can be misused in the future also. Besides, statistics give probabilities only, which are not understood by some courts.

30.4.4 Forensic Psychotherapy

Forensic psychotherapy has come up in a big way, as help, to the criminal in the criminal justice system. As the very name indicates, it means psychological treatment of the offenders, victims or even of the witnesses to further the cause of justice. It takes many forms:

1. Culprits, victims or witnesses who are dazed, may need psychotherapy to normalise them.
2. Some accused persons are emotionally so upset that they are not in a position to stand trial. Psychotherapy stabilises them and thus enables them to stand trial.
3. Psychotherapy helps victims and witnesses to remember details of the occurrence, which they have forgotten.

4. Psychotherapy allows assessment of whether a person is telling truth or lies. The treatment can convert a liar into a truthful person.
5. Psychotherapy has been extensively utilised in treatment of offenders, especially of juvenile delinquents, first offenders and all those who have been assessed to be amenable to psychotherapy.
6. Psychotherapy is being introduced in jails to make the inmates useful citizen after their release from the jails.
7. Psychotherapy is being used increasingly for de-addiction and curing drunkenness.

30.4.5 Forensic Psychological Consultancy

Forensic psychologist, as a consultant, is playing an increasingly important role in the dissemination of justice. He is being consulted by:

1. **Courts;** about the dangerous potential of a criminal to the society, about the personalised punishment to the offender, in order to inflict minimum damage to his personality, consistent with the fact that justice is also being done to the victim/society. He is consulted to stabilise accused, victims and witnesses in trials.
2. **Advocates;** for their clients to find out if:
   - The client is fit to stand trial or not.
   - The plea of temporary insanity at the time of commission of crime can be taken or not.
   - The mental age of the offender can be proved to be such that punishment, alternative to imprisonment, could be pleaded.
   - If the provocation of the victim, beyond tolerance limit, could be shown as defence plea.
3. **Family matters:** the need for consultancy in family problems is becoming more pressing, especially relating to the custody of the child. Whether the custody of the father or the mother or of a third party would be in the interest of the child, often calls for the opinion of a forensic psychologist. This is especially so when the parents (one or both) have unsociable or criminal tendencies and background.

   Forensic psychologists are being consulted increasingly in marriage or divorce problems by the society and the courts.
4. **Rehabilitation of prisoners:** The services of forensic psychologists are being utilised increasingly in handling and rehabilitation of the prisoners. Their services are becoming indispensable in cases of juvenile delinquents, to determine the patterns of treatment to normalise their psychological and social personalities. The psychological treatment of the impulsive criminal is being envisaged increasingly.

30.5 PROBLEMS/POSSIBILITIES

Forensic psychology is expanding its ramifications in all aspects of the criminal justice system, with the passage of time. It currently provides answers to the following types of questions:

1. Can the subject, accused of a crime, be assigned criminal responsibility?
2. Is the subject competent to stand trial, wave his constitutional rights or execute a contract or a will, in view of the alleged malfunctioning of his brain?
3. Can the psychologically incompetent subject be made competent by psychotherapy to perform his legal obligations?

4. Does the subject suffer from a brain injury, if so, to what extent?
5. Was the subject, at the time of the commission of crime temporarily insane or dazed, due to emotional breakdown, the influence of drugs or liquors or due to physical injury, to claim diminished responsibility?
6. Is the subject suffering from amnesia? If so, what are its nature and the extent? Or, is he shamming amnesia to avoid criminal responsibility?
7. Does the subject have criminal tendencies? Has he committed a crime(s) previously?
8. Has the employee committed a crime? Is he likely to commit crime again?
9. Can the criminal be treated to stop recidivism?
10. Is it possible to remove the stigma of imprisonment from the mind of the subject?
11. What should be appropriate punishment to the subject, especially if he happens to be new to the crime or is a young person? Imprisonment? Fine? Suspended sentence? Probation? Restitution? Or, can psychotherapy help and replace conviction?
12. Is psychotherapy useful to all prisoners? Or, which prisoners will be amenable for treatment?
13. Should the given juvenile be treated as an adult because of his quicker mental, physical and emotional development?
14. Did the subject make a true or false confession?
15. Are the victim(s), culprit(s) and the witnesses telling the truth?
16. Does the subject have suicidal tendencies?
17. Are the alleged obscene communications or the phone calls genuine or phony?
18. Is the mental aberration of the subject sufficiently acute to warrant his dispatch to a mental asylum?
19. Does the repeated violence of husband and wife *inter se* indicate marital incompatibility?
20. How can the interests of the child be served best, by giving the custody of the child to mother, to father or to a third party?

In addition, forensic psychology helps to:

1. Identification basis of a subject
2. Identification of the schizophrenic (or the like) persons
3. Building a personality profile of the subject from his writings (psycho-linguistics), action and behaviour while committing the crime; or, from the *modus operandi*.

30.6 COLLECTION OF EVIDENCE

The following are the sources for forensic psychological evidence:

1. Case history studies
2. Covert and overt observations
3. Interviews and interrogations
4. Experiments
5. Research

30.6.1 Case History Studies

In all psychological evaluations, case history study forms the first step towards the goal. This involves the study of the behaviour of the subject in the past for as long a period as possible along with his current behaviour towards all concerned. The sources for the information are mainly:

1. **The family:** parents, brothers and sisters, husband or wife, as the case may be, sons, daughters and relatives living with the family or visiting the family frequently
2. **Family friends:** who know the family and the subject intimately
3. School and college-mates and other friends of the subject
4. Partners, colleagues, superiors and subordinates who frequently meet the subject
5. Club members and its staff, if the subject is a member of the club
6. Contribution and behaviour of the subject in governmental or non-governmental organisations, if he is a member of the organisations

Case studies provide a wealth of information about the behaviour and personality of the subject if the studies are carried out meticulously.

30.6.2 Observations

The case histories of the subject(s) are highly valued in the total evaluations. They are not often complete or truthful because sometimes biased information is given by the interviewees intentionally or otherwise. Besides, they are not professional observers. Consequently, they often miss important details essential to build a correct psychological profile of the subject. Observations by the forensic psychologist are, therefore, essential. The observations are made in all aspects of the subject's life: at home, in the office, in the social dealings, execution of business, and religious activities. The observations have to be spread over a period consistent with the need of the case. However, the limitations imposed by the court and the counsel have to respected. The observations lead to a proper psychological profile.

30.6.3 Interviews and Interrogations

Interviews and interrogations form the backbone of psycho-diagnostic processes. Case studies are good, but the available details are often limited and their trustworthiness is not always certain. Likewise, observations are a good source of information, but they are time-consuming and in actual fieldwork, they are often not practical due to the time and budget constraints. Interviews and interrogations consume less time, and in competent hands, they can work wonders.

The success in interrogation and interviews depends upon if:

1. The psychologist knows the background of the subject and the incident, which has necessitated the psychological appraisal. The psychologist start interviews only after acquiring the information.
2. The psychologist conducts interviews in a relaxed atmosphere.
3. He does not stretch the interview period of the interview to cause boredom, fatigue or depression. Often more than one interview is needed to reach the inner reaches of the subject.
4. The psychologist is able to win his confidence of the subject that he is with him and whatever he is doing is for his benefit.

5. The psychologist understands what ticks the subject and what ticked him to a given action.
6. The psychologist is able to establish a personal rapport with the subject. Once this rapport is achieved the subject opens up and provides all the data to reconstruct his psychological profile to give answers to various questions like why? What for? When? Who? Where? How?

The interviews are conducted in special rooms (clinics) ideally. The room has to be free of all sorts of distractions. No other person other than the psychologist and the subject should be present in the room. If the dialogue is to be recorded, it should be done covertly. Sometimes makeshift arrangement has to be made when the subject is in jail or in a hospital. Even in these situations, the principle of privacy is observed. Some psychologists carry their own tents with them to the site; others requisition them at the site from the authorities of the institutions.

30.6.4 Experimental Approach

Among the various approaches in forensic psychology, the experimental approach provides the most convincing evidence.

> *The first-ever-case of experimental psychology saved a train driver from conviction in a case of train accident. The charge was that the driver failed to stop the train in time and thus caused the death of the victim. Forensic psychologist showed experimentally that the response time in this case was short and the driver could not stop the train given the same speed and distance to stop. The judge appreciated the experiment and acquitted the driver. (CH)*

The nature of the experimental work varies according to the type of the case. The following examples illustrate the nature and effectiveness of experimental approach:

> *In a case of road accident the claimant alleged that he could not use his left leg. An experiment was organised covertly. While he was limping on the road, a cracker was exploded behind his back. The claimant thinking it an explosion of a bomb ran fast. The act of running was videographed (covertly). The video show finished the claimant's claim. (CH)*

> *An airman was charged for acts of omission and commission. He claimed temporary insanity due to influence of drinking. He was made to drink the same quantity of same illicit liquor in the same interval. Not only he became drunk, but he was violent also. In addition, his condition deteriorated so much that he had to be hospitalised for considerable period. On the affidavits of the witnesses who observed the drinking experiment and its aftermath, the charges against him were withdrawn. (CH)*

30.7 PSYCHOLOGY IN INTERROGATION

Police interrogators have been using psychology in their interrogation from time immemorial without involving the name of psychology. They used all types of emotions: fear, hatred, revenge, greed, love, pain in their interrogation to get at the truth. Pain and fright were the most frequently used emotions and they often proved effective in extracting the truth. The interrogator would use III Degree methods to frighten the subject so frequently and so severely that the III degree became most infamous. So much so that even today many suspects die in **"police interrogations"** because of III degree methods. The methods have become so notorious that some innocent people **"confess"** to the crime they have not seen, to avoid police brutality. Thus, pain and fright worked.

With advances in the understanding of human behaviour, forensic psychology developed and its interrogation aspects flourished most conspicuously. Forensic psychology has been in the field of detection of deception, commonly known as lie detection, for about a century now. It has come up in a big way to get at the truth. The following modes are used extensively. Simultaneously they are being refined.

1. **Psycho-physiological Detection of Deception (PDD)**, commonly known as Lie Detection.
2. **Narco-analysis;** Media persons and fiction writers have given it the fancy name 'Truth Serum.
3. **Brain Printing**; Brain Electrical Activated Oscillation (BEAO).
4. **Hypnosis.**
5. **Psychological Stress Evaluator (PSE)**.

30.7.1 Psycho-physiological Detection of Deception (PDD)[2]

The detection of deception is also known as Lie Detection or finding the truth. Psycho-physiological mode of the detection of deception is one big step forward in crime handling. Polygraph is the most frequently used device for lie detection. It is also known as a Lie Detector.

Lie detection process had its origin from the studies of psychosomatic disorders, (also known as psycho-physiological disorders) by psychologists, psychiatrists and physiologists. Psychosomatic disorders are certain disorders of the body, or soma, due to psychological events, such as welling up of strong emotions. The theory emphasises a close relationship between "body" and "mind" and the interaction between the two is named psycho-physiological interaction. The interaction of emotion and body, when a person tells lies, causes certain changes in the body. These changes are detected through instruments and the process is called lie detection by the common man. The other name given to the lie detection is "Psycho-physiological Detection of Deception" (PDD). It can also be named as "Truth Verification".

Although the theory of psychosomatic interaction appears to be a new development, yet historically it is as old as human thinking about mind and matter. There are enough instances where this theory had been successfully applied for medical diagnosis. Now this psychosomatic interaction is extensively used in lie detection or in truth verification.

The term psychosomatic interaction means that when a person faces the problem of answering question(s) relating to a crime in which he is involved has to decide what answer he should give. If he gives true answers his life and liberties will be in jeopardy. He has to coin some lie for self-preservation. In this mental exercise, the individual suffers certain visible and invisible physiological disturbances. The subtle (invisible) ones are detected through instrumental recordings, recorded in the forms of graphs. The evaluations of the graphs indicate the answers, which are lies. Thus, the emotions and thinking of the subject can be visualised from the physiological manifestations and *vice versa*.

The first scientific use of this principle for crime investigation dates back to 1895 when Lombroso conducted experiments on actual criminal suspects and demonstrated that there is a change in the suspect's blood pressure and pulse rate when he tells a lie. From 1914 onwards, the experiments were seriously pursued to establish that the feeling of guilt in a culprit induces fear (fear of exposure and entrapment). It brings in physiological changes. The blood pressure, the pulse rate and the respiration are affected prominently. The experiments also indicated that these reactions are governed by the automatic nervous system of the body and, therefore, lie, generally, beyond the conscious control of most of the individuals.

30.7.2 Psychological Stress Evaluator

Psychological stress evaluator (PSE) is an instrument like the lie detector. It detects the stress on the subject, which he undergoes while telling lies. Part of this stress may be revealed in his

2. For more details see chapter 31, on Detection of Deception.

voice, but mostly it is found in the inaudible vibrations (tremors) which the speaker under stress emits from the voice organs (vocal cord). The instrument records these inaudible tremors and thus indicates the falsehood or truthfulness of his statements.

The subject is asked to answer simple but well-organised questions. Questions which are not related to the crime (Irrelevant Questions), which the subject will answer truthfully, and questions which relate to the crime (Relevant Questions), where the subject tells lies, if he is the culprit. Relevant Questions and Irrelevant Questions are carefully intermingled. The inaudible vibrations are then recorded on a magnetic tape. This tape is then "fed" into the P.S.E. that differentiates truth from falsehood in the same ways as the lie-detector does.

The instrument is claimed to be superior to polygraph. It can be used covertly. It is simpler, less bulky — only a tape recorder need be used during interrogation. A second expert can check/verify the recorded evidence. It can be used to evaluate recorded telephonic conversations.

The P.S.E. has not become popular yet.

30.7.3 Hypnosis

Hypnosis is the process in which the subject (person under interrogation) accepts the suggestion of the hypnotist non-critically. The reasoning faculty of the individual is suppressed.

Hypnosis has been used successfully in medicine. It is being used in the criminal investigation in the following situations:

1. When the victim has forgotten the details due to extreme fright or emotional breakdown.

   In a case of murder (of one girl) and rape (of a second girl), the second was so frightened that she could not give the details of the culprit. She was put under hypnosis. She gave complete details. When the facial features reconstructed from her description given under hypnosis, and the portrait drawn from the description, was shown she at once exclaimed that he was the culprit. (CH).

2. Mendacious witnesses tell the truth under hypnosis.
3. Malingerers, who fake physical injuries, are exposed.
4. Falsehood of a charge preferred against a person can be checked.
5. The culprit, under hypnosis, may disclose the hidden case property/clues, such as *corpus delicti*, *the* weapon of offence.

In addition, hypnosis helps in building character in police officers, toughens in spies and saboteurs, fanaticism among terrorists.

Hypnosis is a double-edged weapon. It can be misused by the criminals:

1. Persons can be induced to commit crime under the hypnotic suggestion — the extent to which a subject can go depends upon the personalities of the subject and the hypnotist, especially on the latter's skill.

   In a recent case, a Tantaric inveigled a rich widow to become his disciple. With passage of time, he not only won her complete confidence but became intimate also. The Guru had an eye on her property. He hypnotised her so well that she got his name entered as the authorised person to operate her bank lockers also. In addition, he got a sale deed of her flat executed in his favour without paying any money. Later he persuaded her to create a trust of her vast landed property. He got himself nominated as the chief executive of the trust. At this stage the hypnotic spell went off. She hauled up the Tantaric in the courts to recover her property. (CH)

2. Persons can be hypnotized to gift away their property.
3. Persons can be induced to give false confessions, false *alibi*, or made to forget certain events, including criminal acts, like forgeries.
4. Hypnosis is being used to inveigle the Fidayeen to form suicide bombers on large scale.

Hypnosis has yet to travel a long way to become an accepted technique in police investigations in India. However, the potential is unlimited. It is especially useful where children, women and nervous persons are involved as victims or witnesses. They perform better under hypnosis.

30.7.4 Narco-analysis[3]

It is believed that if a person is administered a drug which suppresses his reasoning power without affecting memory and speech, he can be made, to tell the truth. Some drugs have been found to create this twilight state in some persons. These drugs are being administered in some countries including India.

Truth serums (or sera) are no serum at all. They are drugs, sometimes used clinically. A few of the best-known drugs are Sodium Pentothal, Sodium Amytal, Seconal, Hyoscine (scopolamine), Phenobarbital. These drugs are administered through injections. They produce a state of semi-conscious in the subject. The reasoning faculty of the individual is suppressed.

Truth drug administration suffers from many drawbacks. *Firstly*, the person to administer them has to be a highly qualified physician. *Secondly*, it is always difficult to determine the correct dose of the drug. It varies with the physical constitution of the subject, his mental attitude, will power and the habituation. Besides, the clever subjects hoodwink the operator by pretending that he is in the state of semi-consciousness. He then tell lies, which are useful to him and which mislead the investigator.

Truth drugs have never been popular in police interrogation anywhere, till recently. They have now being used extensively in important cases. They were used to interrogate spies only where dose could be changed and correct dose found by experiment especially when the instrumental methods have failed to extract the truth. Now Narco-analysis is being used in cases where other techniques proved ineffective. *Nithari Serial murders* case, *Telgi's super stamp scam* case, Abu Salem's 1993 Mumbai blast case and many other cases have brought Narco-analysis in limelight. The recent judgment of the Supreme Court has regulated the test. The consent of the subject has been made essential for the test. The judgment has conferred respectability to the test. It will flourish and thus reduce the number of cases where torturous III degree methods are used.

30.7.5 Brain Printing/Profiling

Brain printing/profiling is based upon the study of the brain's additional electrical activities, stimulated by the visual recognition of familiar associative evidence. The created additional electrical activities indicate that the subject has recognised the given object. An instrument, Encephalograph, has been developed and patented to study these electrical activities.

When a culprit, victim or witness is shown an object, a scene or a situation, which is connected with the crime, his brain recognises the entity. Recognition creates activity in the brain. This activity is recorded by Encephalograph and the trace thus obtained is called Electroencephalogram (EEG).

The brain printing can provide useful information if the following basics are met with:

1. There should be a reliable measure to record the brain stimulation — this has been achieved through electroencephalograph (EEG).
2. The existence or absence of the information with the subject. It is indicated by the response of the subject in the electroencephalograph.

3. See chapter 32 on Narco-analysis.

3. Brain printing is based upon the premise that the individual cannot control his brain activity. The correctness or otherwise of the premise has not been proved so far.

30.7.5.1 Importance

The brain is a storehouse of all the information a subject possesses. If the subject is involved in a particular activity, he has the information stored in his brain. All the criminals and their associates have information about their criminal acts. Therefore, if we can reach this information in the brain, we can establish their involvement or innocence and also the part played by them in a particular act. Thus, it can provide foolproof evidence against them without external sources such as written or oral evidence. As brain of the culprit always records the occurrence, therefore the evidence is always available. Recent advances in neuro-sciences have given a ray of hope that the stored information in the brain can be tapped accurately, non-invasively and objectively which can provide clinching evidence in a crime situation. However, the techniques involved need a lot of spadework before they can provide through brain printing. It will be a big break-through (perhaps the biggest) in scientific criminal investigations.

According to its protagonists it is useful specifically in:

1. White collar crimes
2. Burglary and theft cases
3. Offences against person, including murder and rape cases
4. Identification of terrorist, saboteurs, spies, arsonist.
5. Identification of potential criminals/crime situations

The advantages of the technique are claimed to be:

1. Always available evidence
2. Accurate
3. Cost effective
4. Time effective
5. Non-invasive
6. Quick
7. No subjective element (computer process the details and interpretation) hence no bias
8. Human-right savvy

30.7.5.2 Process

The process of brain printing is simple. It involves:

1. Sensors are strapped around the head in the form of a band.
2. A number of pictures (crime-relevant/crime-irrelevant) are shown to the subject. The culprit's involvement is indicated by the electrical activity of the brain when crime related pictures are shown. The subject should show no additional brain electrical activities when non-crime related pictures are shown. The innocence of the subject is proved by the absence of the electrical activities when the subject is shown the mixed pack of pictures.

3. The brain activity is picked up by the sensors and recorded in a computer in a waveform. The electrical activity changes if the subject recognises any familiar object, action or word at the screen.
4. The analysis of the changes in the wave pattern indicates whether the subject recognised the particular object, action or word, relevant to the crime and shown on the TV screen or not. If the subject was the culprit or a partner, he would recognise the item and the fact is found from the waveform. If the subject is innocent the item would not stimulate brain activity and hence no additional electrical activity will take place. In this process, unlike the polygraph method, no questions are asked.

Brain printing technique to collect evidence is highly attractive. However, there are many rough corners which need smoothing before it becomes a respectable routine technique in the criminal justice system.

In India, Forensic Psychology is making its mark in criminal investigation and trials and thus helping dissemination of justice in a better way. Its tremendous potentiality is bound to make inroads and gets its rightful place in the criminal justice system. There is no doubt that Forensic Psychology is a potent weapon in the fight against crime and handling criminals, to reduce their number, to induce them to follow the path on the right side of the law. The younger generations are finding it tough to compete, to be one with the Joneses and to lead a satisfied life. The society has lost faith in religion and social values. They are increasingly marching towards crime. They need help to avoid downhill slide. Psychology, in general, and Forensic Psychology, in particular, can and has to help to avoid the fall.

30.9 CASE LAW

30.9.1 SC on Narco-analysis/Polygraph/Brain Electrical Activation (Beap) Tests[4]

Author's Summary

This is an unfortunate negative landmark SC judgment on noetic sciences, namely, *polygraph/ /narco-analysis/the Brain Electrical Activation Profile (BEAP)* tests. It disallowed their effective use as evidence in courts and allowed their use in investigation only, subject to the consent of the accused.

The ruling, thereby, tacitly allowed the investigators to use their traditional III Degree modes in interrogation. It, thus, promote inhuman treatment of the suspect under interrogation.

The SC has ruled that for voluntary use of these scientific tests, the guideline provided by the Human Right Commission must be followed scrupulously.

1. The legal questions in this batch of criminal appeals relate to the involuntary administration of certain scientific techniques, namely narcoanalysis, **polygraph examination and the Brain**

4. *Mst. Selvi v State of Karnataka,* AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

Electrical Activation Profile (BEAP) test for the purpose of improving investigation efforts in criminal cases.

1. This issue has received considerable attention since it involves tensions between the desirability of efficient investigation and the preservation of individual liberties. Ordinarily the judicial task is that of evaluating the rival contentions in order to arrive at a sound conclusion. However, the present case is not an ordinary dispute between private parties. It raises pertinent questions about the meaning and scope of fundamental rights which are available to all citizens. Therefore, we must examine the implications of permitting the use of the impugned techniques in a variety of settings.

2. Objections have been raised in respect of instances where individuals who are the accused, suspects or witnesses in an investigation have been subjected to these tests without their consent. Such measures have been defended by citing the importance of extracting information which could help the investigating agencies to prevent criminal activities in the future as well as in circumstances where it is difficult to gather evidence through ordinary means. In some of the impugned judgments, reliance has been placed on certain provisions of the Code of Criminal Procedure, 1973 and the Indian Evidence Act, 1872 to refer back to the responsibilities placed on citizens to fully co-operate with investigation agencies. It has also been urged that administering these techniques does not cause any bodily harm and that the extracted information will be used only for strengthening investigation efforts and will not be admitted as evidence during the trial stage. The assertion is that improvements in fact-finding during the investigation stage will consequently help to increase the rate of prosecution as well as the rate of acquittal. Yet another line of reasoning is that these scientific techniques are a softer alternative to the regrettable and allegedly widespread use of 'third degree methods' by investigators.

3. The involuntary administration of the impugned techniques prompts questions about the protective scope of the 'right against self-incrimination' which finds place in Article 20(3) of our Constitution. In one of the impugned judgments, it has been held that the information extracted through methods such as 'polygraph examination' and the 'Brain Electrical Activation Profile (BEAP) test' cannot be equated with 'testimonial compulsion' because the test subject is not required to give verbal answers, thereby falling outside the protective scope of Article 20(3). It was further ruled that the verbal revelations made during a narcoanalysis test do not attract the bar of article 20(3) since the inculpatory or exculpatory nature of these revelations is not known at the time of conducting the test. To address these questions among others, it is necessary to inquire into the historical origins and rationale behind the 'right against self-incrimination'. The principal questions are whether this right extends to the investigation stage and whether the test results are of a 'testimonial' character, thereby attracting the protection of Article 20(3). Furthermore, we must examine whether relying on the test results or materials discovered with the help of the same creates a reasonable likelihood of incrimination for the test subject.

4. We must also deal with arguments invoking the guarantee of 'substantive due process' which is part and parcel of the idea of 'personal liberty' protected by article 21 of the Constitution. The first question in this regard is whether the provisions in the Code of Criminal Procedure, 1973 that provide for 'medical examination' during the course of an investigation can be read expansively to include the impugned techniques, even though the latter is not explicitly enumerated. To answer this question, it will be necessary to discuss the principles governing the interpretation of statutes in light of scientific advancements. Questions have also been raised with respect to the professional ethics of medical personnel involved in the administration of these techniques. Furthermore, article 21 has been judicially expanded to include a 'right against cruel, inhuman or degrading treatment', which requires us to determine whether the involuntary administration of the impugned techniques violates this

right whose scope corresponds with evolving international human rights norms. We must also consider contentions that have invoked the test subject's 'right to privacy', both in a physical and mental sense.

5. The scientific validity of the impugned techniques has been questioned and it is argued that their results are not entirely reliable. For instance, the narcoanalysis technique involves the intravenous administration of sodium pentothal, a drug which lowers inhibitions on part of the subject and induces the person to talk freely. However, empirical studies suggest that the drug-induced revelations need not necessarily be true. Polygraph examination and the BEAP test are methods which serve the respective purposes of lie-detection and gauging the subject's familiarity with information related to the crime. These techniques are essentially confirmatory in nature, wherein inferences are drawn from the physiological responses of the subject. However, the reliability of these methods has been repeatedly questioned in empirical studies. In the context of criminal cases, the reliability of scientific evidence bears a causal link with several dimensions of the right to a fair trial such as the requisite standard of proving guilt beyond

'Brain Electrical Activation Profile test',

…..also known as the **'P300 Waves test'**. It is a process of detecting whether an individual is familiar with certain information by way of measuring activity in the brain that is triggered by exposure to selected stimuli. This test consists of examining and measuring 'event-related potentials' (ERP), *i.e.*, electrical wave forms emitted by the brain after it has absorbed an external event. An ERP measurement is the recognition of specific patterns of electrical brain activity in a subject that are indicative of certain cognitive mental activities that occur when a person is exposed to a stimulus in the form of an image or a concept expressed in words. The measurement of the cognitive brain activity allows the examiner to ascertain whether the subject recognised stimuli to which he/she was exposed. [Cited from: Andre A Moenssens, '*Brain Fingerprinting - Can it be used to detect the innocence of persons charged with a crime?*' 70 University of Missouri at Kansas City Law Review 891-920 (Summer 2002) at p. 893]

By the late 19th century it had been established that the brain functioned by emitting electrical impulses and the technology to measure them was developed in the form of the electroencephalograph (EEG) which is now commonly used in the medical field. Brain wave patterns observed through an EEG scan are fairly crude and may reflect a variety of unrelated brain activity functions. It was only with the development of computers that it became possible to sort out specific wave components on an EEG and identify the correlation between the waves and specific stimuli. The P300 wave is one such component that was discovered by Dr. Samuel Sutton in 1965. It is a specific event-related brain potential (ERP) which is triggered when information relating to a specific event is recognised by the brain as being significant or surprising.

The P300 waves test is conducted by attaching electrodes to the scalp of the subject, which measure the emission of the said wave components. The test needs to be conducted in an insulated and air-conditioned room in order to prevent distortions arising out of weather conditions. Much like the narcoanalysis technique and polygraph examination, this test also requires effective collaboration between the investigators and the examiner, most importantly for designing the stimuli which are called 'probes'. Ascertaining the subject's familiarity with the 'probes' can help in detecting deception or to gather useful information. The test subject is exposed to auditory or visual stimuli (words, sounds, pictures, videos) that are relevant to the facts being investigated alongside other irrelevant words and pictures. Such stimuli can be broadly classified as material 'probes' and neutral 'probes'. The underlying theory is that in the case of guilty suspects, the exposure to the material probes will lead to the emission of P300 wave components which will be duly recorded by the instruments. By examining the records of these wave components the examiner can make inferences about the individual's familiarity with the information related to the crime. [Refer: Laboratory Procedure Manual –

Brain Electrical Activation Profile (Directorate of Forensic Science, Ministry of Home Affairs, Government of India, New Delhi - 2005)]

The P300 wave test was the precursor to other neuroscientific techniques such as 'Brain Fingerprinting developed by Dr. Lawrence Farwell. The latter technique has been promoted in the context of criminal justice and has already been the subject of litigation. There is an important difference between the 'P300 waves test' that has been used by Forensic Science Laboratories in India and the 'Brain Fingerprinting' technique. Dr. Lawrence Farwell has argued that the P300 wave component is not an isolated sensory brain effect but it is part of a longer response that continues to take place after the initial P300 stimulus has occurred. This extended response bears a correlation with the cognitive processing that takes place slightly beyond the P300 wave and continues in the range of 300-800 milliseconds after the exposure to the stimulus. This extended brain wave component has been named as the MERMER (Memory-and-Encoding-Related-Multifaceted-Electroencephalographic Response) effect. [*See* generally: Lawrence A. Farwell, '*Brain Fingerprinting: A new paradigm in criminal investigations and counter-terrorism*', (2001) Text can be downloaded from <www.brainwavescience.com>]

71. Functional Magnetic Resonance Imaging (FMRI) is another neuroscientific technique whose application in the forensic setting has been contentious. It involves the use of MRI scans for measuring blood flow between different parts of the brain which bears a correlation to the subject's truthfulness or deception. FMRI-based lie-detection has also been advocated as an aid to interrogations in the context of counter-terrorism and intelligence operations, but it prompts the same legal questions that can be raised with respect to all of the techniques mentioned above. Even though these are non-invasive techniques the concern is not so much with the manner in which they are conducted but the consequences for the individuals who undergo the same. The use of techniques such as 'Brain Fingerprinting' and 'FMRI-based Lie-Detection' raise numerous concerns such as those of protecting mental privacy and the harms that may arise from inferences made about the subject's truthfulness or familiarity with the facts of a crime. [*See* generally: Michael S. Pardo, *'Neuroscience evidence, legal culture and criminal procedure*', 33 *American Journal of Criminal Law* 301-337 (Summer 2006); Sarah E. Stoller and Paul Root Wolpe, *'Emerging neurotechnologies for lie detection and the fifth amendment',* 33 *American Journal of Law and Medicine* 359-375 (2007)].

72. These scientific techniques could also find application outside the criminal justice setting. For instance, Henry T. Greely (2005, Cited below) has argued that technologies that may enable a precise identification of the subject's mental responses to specific stimuli could potentially be used for market-research by business concerns for surveying customer preferences and developing targeted advertising schemes. They could also be used to judge mental skills in the educational and employment-related settings since cognitive responses are often perceived to be linked to academic and professional competence. One can foresee the potential use of this technique to distinguish between students and employees on the basis of their cognitive responses. There are several other concerns with the development of these 'mind-reading' technologies especially those relating to the privacy of individuals. [Refer: Henry T. Greely, 'Chapter 17: The social effects of advances in neuroscience: Legal problems, legal perspectives', in Judy Illes (editor), *Neuro-ethics* – Defining the issues in theory, practice and policy (Oxford University Press, 2005) at pp. 245-263] 73. Even though the P300 Wave component has been the subject of considerable research, its uses in the criminal justice system have not received much scholarly attention. Dr. Lawrence Farwell's 'Brain Fingerprinting' technique has attracted considerable publicity but has not been the subject of any rigorous independent study. Besides this preliminary doubt, an important objection is centred on the inherent difficulty of designing the appropriate 'probes' for the test. Even if the 'probes' are prepared by an examiner who is thoroughly familiar with all aspects of the facts being investigated, there is always a chance that a subject may have had prior exposure to the material

probes. In case of such prior exposure, even if the subject is found to be familiar with the probes, the same will be meaningless in the overall context of the investigation. For example, in the aftermath of crimes that receive considerable media-attention the subject can be exposed to the test stimuli in many ways. Such exposure could occur by way of reading about the crime in newspapers or magazines, watching television, listening to the radio or by word of mouth. A possibility of prior exposure to the stimuli may also arise if the investigators unintentionally reveal crucial facts about the crime to the subject before conducting the test. The subject could also be familiar with the content of the material probes for several other reasons.

74. Another significant limitation is that even if the tests demonstrate familiarity with the material probes, there is no conclusive guidance about the actual nature of the subject's involvement in the crime being investigated. For instance, a by-stander who witnessed a murder or robbery could potentially be implicated as an accused if the test reveals that the said person was familiar with the information related to the same. Furthermore, in cases of amnesia or 'memory-hardening' on part of the subject, the tests could be blatantly misleading. Even if the inferences drawn from the 'P300 wave test' are used for corroborating other evidence, they could have a material bearing on a finding of guilt or innocence despite being based on an uncertain premise. [For an overview of the limitations of these neuroscientific techniques, *see*: John G. New, 'If you could read my mind - Implications of neurological evidence for twenty-first century criminal jurisprudence', 29 Journal of Legal Medicine 179-197 (April-June 2008)].

30.10 CONCLUSION

221. In our considered opinion, the compulsory administration of the impugned techniques violates the 'right against self-incrimination'. This is because the underlying rationale of the said right is to ensure the reliability as well as voluntariness of statements that are admitted as evidence. This Court has recognised that the protective scope of Article 20(3) extends to the investigative stage in criminal cases and when read with section 161(2) of the Code of Criminal Procedure, 1973 it protects accused persons, suspects as well as witnesses who are examined during an investigation. The test results cannot be admitted in evidence if they have been obtained through the use of compulsion. Article 20(3) protects an individual's choice between speaking and remaining silent, irrespective of whether the subsequent testimony proves to be inculpatory or exculpatory. Article 20(3) aims to prevent the forcible 'conveyance of personal knowledge that is relevant to the facts in issue'. The results obtained from each of the impugned tests bear a 'testimonial' character and they cannot be categorised as material evidence.

222. We are also of the view that forcing an individual to undergo any of the impugned techniques violates the standard of 'substantive due process' which is required for restraining personal liberty. Such a violation will occur irrespective of whether these techniques are forcibly administered during the course of an investigation or for any other purpose since the test results could also expose a person to adverse consequences of a non-penal nature. The impugned techniques cannot be read into the statutory provisions which enable medical examination during investigation in criminal cases, *i.e.* the Explanation to sections 53, 53A and 54 of the Code of Criminal Procedure, 1973. Such an expansive interpretation is not feasible in light of the rule of '*ejusdem generis*' and the considerations which govern the interpretation of statutes in relation to scientific advancements. We have also elaborated how the compulsory administration of any of these techniques is an unjustified intrusion into the mental privacy of an individual. It would also amount to 'cruel, inhuman or degrading treatment' with regard to the language of evolving international human rights norms. Furthermore, placing reliance on the results gathered from these techniques comes into conflict with the 'right to fair trial'. Invocations of a compelling public interest cannot justify the dilution of constitutional rights such as the 'right against self-incrimination'.

> 223. *In light of these conclusions, we hold that no individual should be forcibly subjected to any of the techniques in question, whether in the context of investigation in criminal cases or otherwise. Doing so would amount to an unwarranted intrusion into personal liberty. However, we do leave room for the voluntary administration of the impugned techniques in the context of criminal justice, provided that certain safeguards are in place. Even when the subject has given consent to undergo any of these tests, the test results by themselves cannot be admitted as evidence because the subject does not exercise conscious control over the responses during the administration of the test. However, any information or material that is subsequently discovered with the help of voluntary administered test results can be admitted, in accordance with section 27 of the Evidence Act, 1872.*

The National Human Rights Commission had published 'Guidelines for the Administration of Polygraph Test (Lie Detector Test) on an Accused' in 2000. These guidelines should be strictly adhered to and similar safeguards should be adopted for conducting the 'Narcoanalysis technique' and the 'Brain Electrical Activation Profile' test. The text of these guidelines has been reproduced below:

(i) No Lie Detector Tests should be administered except on the basis of the consent of the accused. An option should be given to the accused whether he wishes to avail such test.

(ii) If the accused volunteers for a Lie Detector Test, he should be given access to a lawyer and the physical, emotional and legal implication of such a test should be explained to him by the police and his lawyer.

(iii) The consent should be recorded before a Judicial Magistrate.

(iv) During the hearing before the Magistrate, the person alleged to have agreed should be duly represented by a lawyer.

(v) At the hearing, the person in question should also be told in clear terms that the statement that is made shall not be a 'confessional' statement to the Magistrate but will have the status of a statement made to the police.

(vi) The Magistrate shall consider all factors relating to the detention including the length of detention and the nature of the interrogation.

(vii) The actual recording of the Lie Detector Test shall be done by an independent agency (such as a hospital) and conducted in the presence of a lawyer.

(viii) A full medical and factual narration of the manner of the information received must be taken on record.

Reasonable doubt and the right of the accused to present a defence. We must be mindful of the fact that these requirements have long been recognised as components of 'personal liberty' under article 21 of the Constitution. Hence it will be instructive to gather some insights about the admissibility of scientific evidence.

30.10.1 Insanity as Defence[5]

We may briefly notice the evidence bearing on the plea of insanity. Since 1958 the appellant was an employee in the Stores Branch of the Northern Railway Headquarters in Baroda House, New Delhi. In 1958 and 1959 he had altercations with other clerks in the office. On May 20, 1959 his superior officer observed that he was prone to lose temper in no time. In his moments of excitement he became dangerous and used to hit his colleagues with anything that he could lay his hands on. But at the time of his greatest excitement he could distinguish between

5. *Jai Lal v Delhi Administration*, AIR 1969 SC 15 : (1969) 1 SCR 140.

right and wrong. After May, 1959 he worked at his desk as a normal man. In March, 1960 he again quarrelled with another clerk. He was suspended and sent for medical examination. At this stage he was suffering from mental illness. On October 12, 1960 he was examined by a psychiatrist who found that he exhibited symptoms of acute schizophrenia and showed disorder of thought, emotion and perception of external realities. The psychiatrist said that he was harbouring certain delusions. The nature of the delusions is not stated. It is not proved particular delusion or hallucination. The appellant was put on a drug named Largactil and was given convulsive electro-theraphy treatment. On January 12, 1961 he was cured of his illness and was advised to join his duties. On resuming his duties the appellant worked in the office in the normal manner.

There is some evidence that on the morning of November 25, 1961 and the preceding night, the appellant complained that he was unwell and took medicine. But on the morning of November 25, he went to his office as usual. He was late in attendance and was marked absent. He applied in writing for one day's casual leave stating that he had an urgent piece of work at home. Nobody noticed any symptoms of mental disorder at that time. He left the office at about 11.30 a.m. and returned home alone. At 1.45 p.m. he stabbed Leela, Parbati and Raghubir with a knife. He concealed the knife and a search for it has proved fruitless. At 2.45 P.M. the investigating officer arrived on the spot, arrested the appellant and interrogated him. He was then found normal and gave intelligent answers. On the same date, he was produced before a magistrate. His brother was then present but the magistrate was not informed that he was insane. On November 27, he was interrogated by an inspector. It does not appear that he was then insane.

On November 30, the appellant's brother filed an application before the committing magistrate stating that the appellant was insane at the time of the occurrence. The appellant was later remanded to judicial custody. On receipt of another application from his brother he was kept under medical observation from December 16 to December 23. On December 19 the medical officer noted that the appellant was indifferent to his surroundings and personal cleanliness, preoccupied in his thoughts muttering to himself, making meaningless gestures, losing track of conversations, given to delayed and repetitive answers and unable to give a detailed account of incidents leading to his arrest. On December 23, he was declared to be a lunatic though not violent. The psychiatrist noted that the appellant had a relapse of schizophrenia and was suffering from disorder of thought, emotion and loss of contact with realities. From his attitude and manner of talk he was found to be aggressive. On September 6, 1962 the psychiatrist reported that the appellant was cured and was in a position to understand proceedings in court. The commitment order was made on January 4, 1963. The trial started in February 1963. The appellant was sane at the time of the trial.

The group of ailments dubbed schizophrenia is discussed in James D. Page's *Abnormal Psychology,* Ch. XI, pages 236 to 261 and Modi's *Medical Jurisprudence and Toxicology,* 14th Ed., pages 349 to 401. Schizophrenia is a general term referring to a group of severe mental disorders marked by a splitting or disintegration of the personality. The most striking clinical features include general psychological disharmony, emotional impoverishment, the dilapidation of thought processes, absence of social rapport, delusions, hallucinations and peculiarities of conduct.

The question is whether the appellant is criminally responsible for the acts done on November 25, 1961. Section 84 of the Indian Penal Code says:

> *Nothing is an offence which is done by a person who, at the time of doing it, by reason of unsoundness of mind, is incapable of knowing the nature of the act, or that he is doing what is either wrong or contrary to law.*

To establish that the acts done are not offences under section 84 it must be proved clearly that at the time of the commission of the act the appellant by reason of unsoundness of mind was incapable of either knowing that the acts were either morally wrong or contrary to law.

The question is whether the appellant was suffering from such incapacity at the time of the commission of the acts. On this question, the state of his mind before and after the crucial time is relevant. There is evidence of a medical character that between October 12, 1960 and January 12, 1961 he was suffering from schizophrenia. He was completely cured of this disease on January 12, 1961 when he resumed his normal duties. He had another attack of this disease in the middle of December, 1961. The attack lasted till September, 1962 when he was found to be normal again. But it is to be observed that the defence witnesses do not say that even during these two periods the appellant was incapable of discriminating between right and wrong or of knowing the physical nature of the acts done by him.

After the appellant was cured of the disease on January 12, 1961 he was found to be normal. He had a highly strong temperament and was easily excitable. But there is positive evidence that even at the moment of his greatest excitement he could distinguish between right and wrong. From January 12, upto November 24, 1961 he attended his office and discharged his duties in a normal manner. On the morning of November 25, 1961 his mind was normal. He went to and from his office all along. He wrote a sensible application asking for casual leave for one day. At 1.45 P.M. he gave normal and intelligent answers to the investigating officers. Nothing abnormal in him was noticed till December 16, 1961.

The thing in favour of the appellant is that though he had a motive for attacking Baburam, no clear motive for attacking the child Leela or Parbati is discernible. But there is clear evidence to show that he knew that his act of stabbing and killing was wrong and contrary to law. He concealed the weapon of offence. The knife could not be recovered in spite of searches. He bolted the front door of his house to prevent arrest. He then tried to run away by the back door. When an attempt was made to apprehend him he ran back to his house and bolted the door. He then tried to disperse the crowd by throwing brickbats from the roof. His conduct immediately after the occurrence displays consciousness of his guilt. He knew the physical nature of stabbing. He knew that the stabbing would kill and maim his victims. On a comprehensive review of the entire evidence the two courts below concurrently found that the defence of insanity under section 84 was not made out. We are unable to say that the verdict of the courts below is erroneous.

If a person by reason of unsoundness of mind is incapable of knowing the nature of the act or that he is doing what is either wrong or contrary to law he cannot be guilty of any criminal intent. Such a person lacks the requisite *mens rea* and is entitled to an acquittal. But it is not established in the present case that the appellant was suffering from this incapacity. The general burden is on the prosecution to prove beyond reasonable doubt not only the *actus reus* but also the *mens rea.* The prosecution satisfactorily discharged this burden. The appellant was not insane at the time of the killing and stabbing and he knew the consequences of his acts. We must hold that he is criminally responsible for the acts.

In the result, the appeal is dismissed.

CHAPTER 31

PSYCHOLOGICAL DETECTION OF DECEPTION (PDD) (LIE DETECTION)

SYNOPSIS

31.1 General 1537
31.2 Scientific Basis 1538
31.3 Interrogation 1539
31.3.1 The Examiner 1539
31.3.2 The Subject 1539
31.3.3 Preparation for Interrogation 1540
31.3.4 Equipment 1541
31.3.5 Techniques 1541
31.3.5.1 Relevant/Irrelevant Question Technique (RIQ) 1541
31.3.5.2 Peak of Tension Technique (POT) 1541
31.3.5.3 Controlled Question Technique (CQT or RCQT) 1542
31.3.5.4 Miscellaneous Techniques 1542
31.3.6 Interpretation 1542
31.4 Legal Muddle 1543
31.4.1 Supreme Court on Polygraph 1544
31.4.2 Polygraph and Article 20(3) of Constitution 1545
31.4.3 Polygraph a New Avatar of III Degree Methods 1546
31.4.4 Public Rights Paramount 1546
31.4.5 Subject's Rights 1547
31.4.6 National 1547
31.5 Application and Utility 1548
31.6 Limitations 1548
31.7 Criticism and Rebuttal 1549
31.8 Legal Status 1550
31.9 Recent Advances 1551
31.9.1 New Input Devices 1552
31.9.2 Non-Invasive Sensors/Transducers 1532
31.10 Additional Readings 1552
31.11 Case Law 1552
31.11.1 Evidence Inadmissible 1552
31.12 Conclusion 1557
31.12.1 Evidence Admissible 1559
31.12.2 Lie Detector Evidence 1559

31.1 GENERAL

Detection of deception via psychophysiological interaction is common all over the world. Thought processes bring in both visible and invisible physiological changes. In old days, only visible changes were utilised to detect deception. Invisible body changes such as changes in heartbeat, blood pressure, breathing etc. came to be associated with thought processes only at the end of the nineteenth century. Twentieth-century saw the use of these subtle body changes for detection of deception increasingly. They are detected through instrumental techniques. These changes in the body take place when the subject is stressed to suppress the truth intentionally in situations where the subject believes that by suppressing the truth he is likely to gain or save himself from the adverse consequence(s) of telling the truth.

Psycho-physiological detection of deception, also known as lie detection or truth verification, is a big leap forward in crime handling. The most important and frequently used mode in the detection is use of an instrument known as Polygraph or Lie Detector. In addition to the police and defence departments, it is being used extensively by many industries, banks, insurance companies and other organisations.

During the early years of 20th century psychosomatic disorders, also known as psycho-physiological disorders were studied a good deal by psychologists, psychiatrists and physiologists.

"Psychosomatic disorders" are certain disorders of the body or soma, which are due to psychological events, such as welling up of strong emotions. The psychosomatic theorists believe that a close relationship between "body" and "mind" exists and the interaction between the two is psycho-physiological interaction. The interaction of emotions and body, when a person tells lies, causes certain changes in the body as seen above, both visible, and invisible. The latter is more subtle and autonomic. They are detected through instruments and the process is called lie detection by the common man; or, "Psycho-physiological Detection of Deception" (PDD) by the psychologists. "Truth Verification" or "Detection of Truth" is also an appropriate name for the process.

Although the theory of psychosomatic interaction appears to be a new development, yet historically it is as old as human thinking about mind and matter. There are enough instances where this theory had been applied successfully for medical diagnosis. Now this psychosomatic interaction is extensively used in lie detection of deception (or truth verification).

The rationale behind the principle is that when a person faces the problem of answering question(s) relating to a crime in which he is involved, he has to decide what answer he should give. He is worried that a truthful answer would attract punishment. He cannot give truthful answer(s) as that would put his life and liberties in jeopardy. He, therefore, has to coin some lie for self-preservation. This mental conflict brings in certain visible and invisible physiological disturbances. The subtle (invisible) ones are detected through instrumental recordings, recorded in the forms of graphs. Thus, the emotions and thinking of the subject are visualised from the physiological manifestations. The evaluations of the graphs indicate their truthful or false nature.

The first scientific use of this principle for crime investigation dates back to 1895 when Lombroso conducted experiments on actual criminal suspects and demonstrated that there is a change in the suspect's blood pressure and pulse rate when he tells a lie. From 1914 onwards, the experiments were pursued more seriously and intensively to establish that the feeling of guilt in a culprit induces fear (of exposure and punishment). The fear, in turn, brings in physiological changes in blood pressure, the pulse rate and the respiration prominently. The experiments also indicated that these reactions are governed by the autonomic nervous system of the body and, therefore, lie, generally, beyond the conscious control of almost all individuals.

The initial polygraph (lie detector) was, in fact, a product of these early experiments. It was, however, around 1920 that Larson and Keeler, for the first time, independently developed instruments, which came to be known as a polygraph. The instrument could simultaneously record an individual's blood pressure, pulse rate and respiration during interrogation. Keeler further refined the instrument by adding the electro-dermal galvanometer to record the electrical resistance of the skin (GSR). It is this version of the instrument, which constitutes the traditional polygraph.

31.2 SCIENTIFIC BASIS

The traditional polygraph works on the principle that perception or consciously held feelings of guilt produce a Defence Mechanism to ward off the impending punishment for the crime. The fear of detection and punishment induces a person to tell lies. This psychological phenomenon causes mental excitation. It is manifested in the form of physiological changes in blood pressure, pulse rate, respiration rate and in the Galvanic (electrical) Skin Resistance, (GSR). Physiologically the effort put forth by the individual in an attempt to conceal the excitation, known as a defence mechanism, stimulates the adrenal glands. The stimulated

adrenal glands secrete the hormone adrenaline, which on entering the bloodstream steps up the blood pressure, pulse rate and respiration of the individual.

The defence mechanism process, briefly, involves the following aspects:

1. The subject is asked about the crime he has committed. He knows that if he answers the question truthfully, he would be punished for the same.
2. He wants to tell lies to avoid punishment.
3. His mental faculties set in to find lies to substitute the truth. Psychologists name this shielding process as 'Defence Mechanism'.
4. The Defence Mechanism (shielding process) interacts with the body and creates physiological changes in the form of increased blood pressure, increased respiration rate, increased heartbeat and lower Galvanic Skin Resistance (GSR).
5. The examiner records the responses simultaneously on a graph paper or in the computer along with the response to neutral questions interspersed in the questionnaire.
6. The psychologist who carried out the interrogation, personally evaluates the responses or he uses computer to evaluate the results.

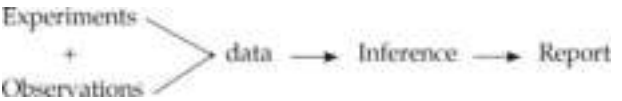
31.3 INTERROGATION

The psychological detection of detection, for successful interrogation, needs a highly sensitive instrument. In addition, other essentials are:

31.3.1 The Examiner

The following features are the hallmarks of an acceptable examiner:

1. **Educational background:** the examiner should have at least a master's degree in Psychology. A Ph. D. inspires greater confidence (Research degree!). Specialisation in Forensic Psychology in an academic career is an additional feather in the cap of the specialist.
2. **Training**; the examiner must have received his basic training from a reputed institution.
3. **Attachment**; the examiner must have been attached to a seasoned Forensic Psychologist for a considerable length of time.
4. **Working experience**; it is indispensable. This is gained through joint examination and issuing joint reports with a senior Forensic Psychologist reporting examiner, for at least fifty cases.
5. Integrity; integrity of the examiner must be above board. His opinion or report must come through the scientific acid test:



31.3.2 The Subject

The examiner must ensure that the subject is in good mental and physical health at the time of polygraph examination

- He is not tired or exhausted. He has not been kept hungry or subjected to physical abuse.
- He is not under the influence of drugs or liquor.

- He has no physical or mental illness.
- He is not nervousness. He is stabilized to the environment by talking to him on matters other than the crime in hand.
- He has given informed consent.

31.3.3 Preparation for Interrogation

The examiner has to do his homework before he can start interrogation. The preparation involves the following elements:

1. **Proper interrogation room:** the set-up of interrogation room plays an important role in achieving accuracy in deception tests. The interrogation is carried out in a Spartan room with one door maximum one window; more or less sound proof, no wall decorations, no bright lighting, no table lamp, no telephone. Only items present in the room are Lie Detector and audio and video recording devices, placed unobtrusively, but not hidden. There is a one-way mirror fitted to the window. It allows a lawyer his client/proceedings through the mirror. The sitting arrangement is for two persons only: the suspect and the examiner. One to one (1:1) arrangement ensures privacy and makes the subject feel at ease.
2. **Background knowledge of the case:** The examiner must know all the facts of the case before starting the interrogation. He usually studies the following documents for the purpose:
   - FIR and inspection report of the scene along with site plan (sketch), photographs and video film of the scene.
   - Statements of the accused, the victim and the witnesses
   - Medico-legal reports of the accused and the victim, if any.
   - Post-mortem report of the victim in case of murder
   - Medical history of the accused, if any
   - Informed consent of the accused[1].
3. **Conference with the investigator:** the conference is essential to understand the case and the needs of the case, to get additional information and to remove informational ambiguities, if any.
4. **Pre-interrogation interview of the subject:** The interview is essential for the interrogator to:
   - Establish a rapport with the subject, to achieve trust/cooperation.
   - Stabilize the subjects, who are usually nervous.
   - 'Acclimatize' the subject with the environment of the interrogation room. The subjects sits in the room for a few minutes, observe the surroundings. There is not much to observe in the room, as it is minimally furnished and not cluttered with office paraphernalia.
   - Familiarize the subject with the interrogation process; its scope, its potentialities, its limitations and expected results so that the usual fear and nervousness of the subject vanishes.

1. The Supreme Court has made it mandatory vide judgment: in the case, *Mst. Selvi v State of Karnataka*, AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

- Inform the subject about the process of interrogation.
- Assess the subject for any abnormality/peculiarity.
- Assess the subject's memory.
- Get the subject's version of the episode and understand its differences from the prosecution version?
- Ascertain the subject's tendency to conceal facts.
- Learn new issues or information, the subject may disclose!

31.3.4 Equipment

In addition to recording equipment the lie detection process uses the following gadgets:

1. **Pneumograph:** it is a corrugated rubber tube. It is tied around the subject's chest. It measures respiratory changes.
2. **Sphygmograph:** it is an inflated cuff. It is wrapped around the upper arm. It measures the cardiovascular changes.
3. **Electrode:** it is attached to the palm or fingers. It measures the Galvanic (electrodermal) Skin Response (GSR).
4. **Plethysmograph: i**t is a transducer. It is attached to the thumb. It measures blood volume reflecting the pulse rate.

All the measurements through the above instruments are recorded simultaneously in the form of traces on a graph paper individually. These graph recordings, are collectively called a Polygram. It is evaluated to find out whether during the test the subject experienced emotional stress from any of the questions asked, or showed no reaction.

31.3.5 Techniques

In questioning the subject, generally the following basic approaches are followed:

31.3.5.1 Relevant/Irrelevant Question Technique (RIQ)

In this technique, both relevant and irrelevant questions, pertaining to the case in hand, are asked. The irrelevant questions to the case under investigation are like:

- 'Is your name Mr. X?' Or,
- 'Did you take tea in the morning?'

The irrelevant questions are interspersed with relevant questions that are related to the crime, such as:

- 'Did you steal the jewellery?' Or,
- 'Did you shoot the victim with a revolver?'

The difference in the physiological response to relevant and irrelevant questions indicates whether the person is telling the truth or is lying.

31.3.5.2 Peak of Tension Technique (POT)

In the Peak of Tension technique, only one pertinent but emotionally charged question, after several control questions, of irrelevant nature, is asked. The irrelevant questions build the tension, which is released after the relevant question has been asked. The technique is

dependent for its usefulness on the fact that a guilty person may possess knowledge that no innocent person could possess. A question regarding this knowledge would produce emotional reactions in a guilty person, while an innocent person would show no reaction to the question.

31.3.5.3 Controlled Question Technique (CQT or RCQT)

In controlled question technique, controlled questions are asked. These questions relate to the associative evidence already known to the examiner. Only the culprit can show a reaction to the questions, as he alone knows them. The questions are inter-mixed with irrelevant questions. The reaction is recorded in the Polygram like the other techniques. The technique is also called after the name of its first user Reid, RCQT, R for Reid.

31.3.5.4 Miscellaneous Techniques

There are many other techniques, similar to the above techniques with some variations in the details; including the following:

- *Multiple General Question Technique MGQT*
- *Guilty Knowledge Test (GKT)*
- *Silent Answer Technique (SAT).*
- *Asking questions to which the subject must lie.*

The details of these are unnecessary for the non-practitioner; hence beyond the scope of this book

31.3.6 Interpretation

The difficult aspect of a lie-detection test, however, is the interpretation of the Polygram. In analysing, evaluating and interpreting a Polygram, the following aspects are carefully considered.

- Simultaneous occurrence of suppression in respiration and increase in blood pressure immediately before the subject's reply
- Decrease in blood pressure several seconds after the reply
- Heavier breathing, 15-20 seconds after the reply, to a relevant question
- Slowing down of subject's pulse beat after the questioning is over and the subject is told that no more questions would be asked of him.
- A general upward trend of the entire blood pressure curve during the test is indicative of tension due to feeling of guilt.
- Interpretation of GSR is based on certain upward movement of the tracings due to changes in the electrical resistance of the skin of the subject.
- Regarding GSR it may, however, be noted that the exact nature of these responses is not yet completely understood. The authorities differ considerably in their opinion. It is rather surprising that although in the experimental deception tests conducted in the laboratory, GSR offers reliable deceptive criteria, in actual field cases similar high degree of accuracy is not often available as in other measurements of physiological responses, such as, blood pressure and pulse.
- Each questionnaire is run three times.

The aspects, which are considered for evaluation and interpretation of the Polygram, will become clear from the illustration given below:

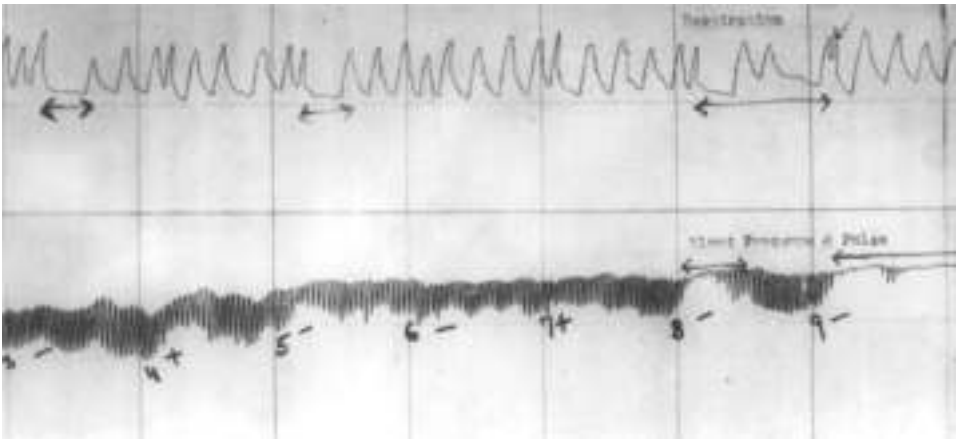


Fig. 31.1

Polygram Showing Respiratory and Cardio-vascular Responses of a Deceptive Subject. Note the Difference in the Response of Relevant Question Nos. 3, 5, 8 and 9 to Irrelevant Question Nos. 4 and 7. Question No. 6 was a Control Question for Toning up the Subject Emotionally.

In a murder case the suspect denied that he had seen the victim after sunset. He also denied the charges that either he committed the murder or knows who committed the offence. In this case, RIQ (relevant/irrelevant question technique) was followed.

1. *'Did you take tea in the morning?'*
2. *'Can you read Hindi newspaper?'*

To arouse the suspect emotionally a control question (S. No. 6) was asked:

6. 'Can you murder someone?'

Questions at S. Nos. 3, 5, 8 and 9 were relevant. They were, respectively:

3. *'Did you see X (victim) after sunset?'*
5. *'Do you have any information as to where did X go after sunset?'*
8. *'Did you murder X?', and lastly,*
9. *'Do you have any knowledge as to who murdered X?'*

The plus (+) and minus (–) signs on the Polygram are indicative of the suspect's reply in affirmative or negative, respectively. The changes in the tracings of respiration, blood pressure and pulse at relevant questions in comparison to irrelevant questions are indicative of deception. Particularly, the suspect's physiological reactions to questions at S. No. 8 and 9 indicate that he was directly involved in the crime which he later admitted to the police when confronted with the test results. (CH)

31.4 LEGAL MUDDLE

There is confusion all round about the legal status of the evidence pertaining to Lie Detection (Truth Verification) techniques. A 2010 judgment of the Supreme Court[2] has restricted the

2. *Mst. Selvi v State of Karnataka*, AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

legal status of the important tools, which have and tend to replace the III Degree methods. The main direction in the judgment is that the tests (Lie Detection, Narco-analysis, Brain Electrical Activated Oscillation, etc.) can be administered only if the subject gives informed consent for the test. This informed consent, largely, was being taken before the test was administered. This simple direction has been enshrouded in so many words (>250 pages!).

Polygraph interrogation is riddled with many legal controversies. The main legal issues, which are discussed in Indian courts, are:

1. Supreme Court Judgment (Supra) on polygraph and other types of psychological interrogation
2. Does (or does not) polygraph interrogation infringe article 20(3) of the Constitution?
3. Do polygraph interrogations tantamount to III Degree treatment of the subject?
4. Does polygraph interrogation fall in the ambit of Evidence Act?
5. Are the rights of the criminal or are the rights of the public at large, paramount?
6. Is polygraph interrogation an invasion on the privacy of the subject?

These issues have to be appraised dispassionately if polygraph interrogation has to be accepted or rejected as a tool of investigation or a potent source of evidence in courts.

31.4.1 Supreme Court on Polygraph

In 2010, a Bench of Supreme Court of India headed by the then Chief Justice of India (who wrote the judgment) has given verdict upon Polygraph and other emerging new branches of Forensic Psychology (supra). The salient features of the judgment, *vis-à-vis* polygraph interrogation are:

1. The polygraph interrogation to be administered only with the consent of the subject before a magistrate.
2. Nobody to be forced to undergo the test involuntarily.
3. The material and other evidence derived from the polygraph interrogation can be used as evidence under section 27 of the Indian Evidence Act.
4. Direct evidence from polygraph interrogation is inadmissible unless supported by other evidence.
5. Involuntary interrogation amounts to III degree methods and the court cannot permit such tests.
6. The compelling public interest cannot justify ignoring right against self-incrimination.
7. Parliament may consider enacting laws to make the involuntary test admissible in compelling public interest cases.

The only setback to the police is that involuntary polygraph interrogation is not allowed. It is unfortunate that in serious crimes where it is needed most to interrogate hardened criminals who would not consent to take the test, the police is deprived of the scientific facility.

It is equally unfortunate that the government failed to put up facts before the court completely and lucidly to show that even involuntary polygraph interrogation is not unconstitutional for the following reasons:

1. Polygraphist just unravels the memory of the subject relating to the incident which is hidden in the fold of the brain. The information so extracted may explicate (or implicate) the subject. The psychologist does not know its value nor does he care for

the same. He just records it through audio and video films. It becomes an evidence only when the investigator evaluates it *vis-à-vis* the circumstances of the case. The contents may be explicatory or implicatory.

In the infamous Nithari serial *murders, polygraph interrogation exonerated, in some cases, Pandher for murder charges where 16 girls were murdered in his own house! (CH)*

The blood from a suspect is drawn with a syringe needle day in and day out for identifying murderers, rapists and other sex criminals, for determining disputed paternity, rape, murder and for other serious or petty crimes. Such blood drawl is not considered unconstitutional in India. Rather courts have ordered drawl of blood in many a case.

N.D. Tewari's (a renowned politician!) was involved in a Disputed Paternity case. He refused to give blood for DNA analysis. Delhi High Court ordered to take the blood forcibly in case he does not give blood as such. He gave the blood. (CH)

In polygraph interrogation, no blood is drawn. Only blood pressure measuring rubber cuffs (like those in therapy) are used and only for a few minutes. These attachments cannot be equated to III Degree torture where the subject is beaten severely and shown many indignities. We cannot have two standards in the dissemination of justice. If use of needle is legal in one type, can it be unconstitutional in other types of cases. Recent developments in technology have improved such devices that the subject hardly feels the presence of those attachments.

2. It is unfortunate that it was not brought to the notice of the court that polygraph interrogation does not cause any pain to the subject and that the prosecution failed to produce expert to explain the process to the court. By no stretch of imagination, who knows the nature of the test, can equate polygraph interrogation with III Degree methods.

3. The Supreme Court in an earlier judgment[3] has clarified that:

   Article 20(3) "**does not say that an accused person cannot be compelled to be a witness".** It says that such a person **"cannot be compelled to be witness against himself".**

   The question, therefore, is whether the accused is "furnishing evidence" against him, in the lie detection. If we consider the extraction of evidence from memory layers by scientific methods then where is the question of the subject furnishing the evidence against himself? He is not furnishing any evidence. It is being taken into possession like other evidence (fingerprints or footprints from an unwilling accused). Taking of fingerprints or footprints or photographs does not attract infringement of article 20(3). On parity, Polygraph interrogation also does not infringe the Article 20(3) of the Constitution.

It is unfortunate that the scientific facts and parity of the evidence with other evidence were not brought to the notice of the court to prevent injustice to polygraph interrogation and other Forensic Psychological techniques.

31.4.2 Polygraph and Article 20(3) of Constitution

Article 20(3) states:

"No person, accused of an offence, can be compelled to be a witness against himself".

The relevant contents of the above have two elements: *firstly,* **'no person accused of an offence can be compelled'** and *secondly*, **'to be a witness against himself'.** It is true that most of the persons put to polygraph interrogation are accused of an offence(s). But neither are they compelled nor they become witness against themselves.

3. *State of Bombay v Kathi Kalu Oghad*, AIR 1961 SC 1808 : (1962) 3 SCR 10 : (1961) 2 Cr LJ 856 (SC).

No one is compelled to give evidence against him. In fact, the consent of the subject is taken before he is subjected to narco-analysis interrogation. In a recent case[4] the Gujarat Laboratory refused to carry out narco-analysis interrogation because the accused refused to give consent for the test. Thus, there is no compulsion to undergo the test. Further, the accused persons are often ready to undergo the test to get themselves explicated of the accusation.

> *In Nithari serial murders there were two accused; Surrender Koli and Mohinder Singh Pandher. Both opted for polygraph interrogation. The test explicated the latter of murdering acts of some of the sixteen girls. (CH)*

The subject undergoing polygraph interrogation is not a witness against himself. In fact, information is being extracted from him like other evidence: blood for DNA analysis, fingerprints and footprints for comparison, etc. The law has allowed the collection of the latter types of evidence even forcibly, against subject's will.

Further, the information is not evidence until it is evaluated. The evaluation may even exonerate the subject of the charge as has happened to Mohinder Singh Panther in some of the recent notorious Nithari serial killing cases.

In polygraph interrogation, the accused (subject) does not become a witness against himself. In fact, he gives wrong answers, which do not implicate him. He does not give the information. The information is extracted by scientific methods by scientists following standard procedures. The evidence obtained is just like the evidence extracted from the accused in murder, rape or other cases in which the culprit leaves blood, flesh, skin, saliva, etc. at the crime scene or with the victim. Information of the source is obtained only when blood is extracted from the accused, analysed and matched with the corresponding data from the incriminating evidence. Both the enacted and case law has allowed the practice. In some cases, even courts have ordered the extraction of blood.[5]

Extraction of evidence through polygraph interrogation by qualified scientists under proper conditions has to be treated at par with the blood extraction of blood evidence if we want to avoid the charge of ignorance, bigotry and judicial chauvinism.

The utility and acceptance, by the courts, of the evidence has to depend upon the quality of evidence, its proper processing and presentation.

In short, polygraph interrogation does not infringe sub-article 20(3) of the Indian Constitution.

31.4.3 Polygraph a New Avatar of III Degree Methods

Polygraph interrogation is no new Avatar of III Degree methods. In fact, as already seen, it gives relief to the subject from III Degree treatment: from pain and indignities. Those who call polygraph interrogation as a new type of III Degree mode are perhaps unaware that modern polygraph interrogation does not inflict any pain; instead, it eliminates pain indignities and even custodial deaths. Consequently, it is blasphemy to equate it with III Degree modes.

31.4.4 Public Rights Paramount

One can understand that no innocent person should be convicted but do our Constitution or lawmakers intend that the criminal be let loose on public on flimsy grounds? Whose interests are the government, the legislature and the judiciary watching and protecting? Are they worried about the public of teaming millions or of a handful of criminals? There can be no two opinions or answers to this question. The rights of the public are paramount.

4. State FSL Gandhinagar Rao case.
5. In *N.D. Tewari's* disputed paternity case, on refusal to give blood, Delhi High Court ordered the accused to furnish blood.

Science has made tremendous progress in recent years. The criminal is using science to the hilt to carry out his nefarious activities. The law keepers are hindered from using modern science: flimsy law points, corruption, avoidable administrative delay, low priority to modernize scientific investigations, etc. Consequence: the criminal gets away with the crime; which emboldens not only him but also others with criminal tendencies. Most of the criminals in heinous crime are acquitted, because:

1. Wrong notions of law and justice
2. Topsy-turvy priorities of the government and of various wings of criminal justice system
   - The government does not create adequate police manpower and scientific facilities including scientific manpower.
   - The police dance attendance upon VIPs instead of making the criminal do the dancing around them.
3. Prosecutors give free hand to the defence lawyers (and courts) for many reasons.
4. The judges are bound to old order. Some years ago a trial judge remarked, "Let me explode the myth of scientific evidence once forever," Others go on prolonging cases for years, again, for no valid reasons.

The sorry state of affairs continues.

The public interest must be made paramount. If the privacy of the culprit, who has shattered the home life of the victim, suffers; nothing is lost. Likewise, if the culprit has to suffer some inconvenience, no harm is done. The subject has to bear such burdens if the public interest, at large, has to be paramount.

31.4.5 Subject's Rights

The critics of polygraph technique emphasise that the technique involves an intrusion into the privacy of the subject. In order to counter such criticism, certain rights of the subject have been formulated. These rights are respected. These are:

- Only a qualified examiner is to examine the subject.
- The subject must be declared fit for polygraph examination.
- He must be informed of the reasons for the polygraph test.
- He should know how the polygraph functions and data is obtained.
- He must consent to take the polygraph test. He can refuse to submit to polygraph test.
- He must not be exposed to mental and physical abuse.
- He must not be subjected to prolonged questioning.

31.4.6 National

The Human Right Commission has issued the following guidelines for the Lie Detection test

(i) No Lie Detector Tests should be administered except on the basis of consent of the accused. An option should be given to the accused whether he wishes to avail such test.

(ii) If the accused volunteers for a Lie Detector Test, he explained should be given access to a lawyer and the physical, emotional and legal implications of such a test should be to him by the police and his lawyer.

(iii) The consent should be recorded before a Judicial Magistrate.

(iv) During the hearing before the Magistrate, the person alleged to have agreed should be duly represented by a lawyer.

(v) At the hearing, the person in question should also be told in clear terms that the statement that is made shall not be a 'confessional' statement to the Magistrate but will have the status of a statement made to the police.

(vi) The Magistrate shall consider all factors relating to the detention including the length of detention and the nature of the interrogation.

(vii) The actual recording of the Lie Detector Test shall be done by an independent agency (such as a hospital) and conducted in the presence of a lawyer.

(viii) A full medical and factual narration of the manner of the information received must be taken on record.

31.5 APPLICATION AND UTILITY

Since the development of polygraph, it has been widely applied in a criminal investigation by the police, especially in the USA and Japan. However, of late, the polygraph has also been used for other purposes:

- Recruitment of police and other personnel.
- Department of defence, banks and other organisations use lie detector as an aid for the investigation undertaken by them.
- The big business and industrial concerns in the USA use the lie detector for checking the honesty of their employees.

Specific utility of polygraph

1. It is time and cost effective method of interrogation.
2. It can expose deception in many situations like malingering.
3. The techniques are humane – they dispense with III Degree methods.
4. Innocent persons escape police harassment as it discriminates between the innocent and the guilty.
5. The test often induces guilty to confess to his crime.
6. It can identify the culprit and his accomplices.
7. It can help locate the *corpus delicti*/hidden evidence/booty .
8. It can check the veracity of the statement of a witness.
9. It can identify the insider fraudster in bank frauds.

31.6 LIMITATIONS

One of the main difficulties in conducting a lie detection test is the nervousness shown by many truthful or innocent subjects under interrogations. The nervousness may be due to fear of being involved in a crime, which he has not committed or due to guilt complex from some other offence committed earlier. Such nervousness is manifested in the polygraph chart by the general erratic character of the tracings (mainly of blood pressure). In such tracings, usually similar type of physiological responses can be observed to both relevant and irrelevant questions (Fig. 28.3).

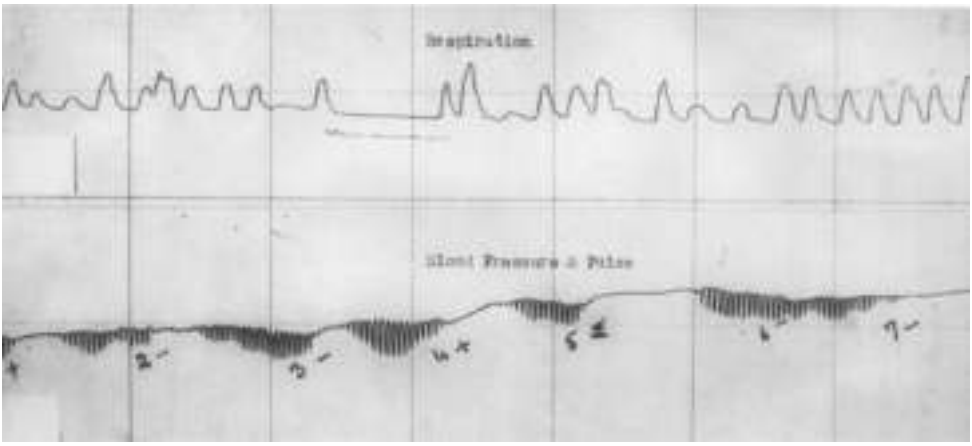

Fig. 31.2

Polygram Showing Respiratory and Cardio-vascular Responses of a Nervous but Truthful Subject. The Subject Reacted Equally to all the Questions Relevant (3 and 5) or Irrelevant (1, 2, 4 & 7). The Control Question at No. 6 Could not Arouse the Subject Emotionally.

A biased attitude of the examiner can affect the diagnosis. If the examiner believes that the suspect is guilty he is prone to find evidence of his guilt on the polygraph chart. Similarly, if he believes that the subject is innocent, he is prone to find evidence of innocence. This is especially true with newcomers in the profession furnish reports without peer participation in the examination.

Other sources of error are the unresponsiveness of the subject; some unobserved muscle movements, physical or mental illness. The examiner must strictly follow the essential conditions for the successful operation of a polygraph. Novice examiners can mess the whole process.

31.7 CRITICISM AND REBUTTAL

The lie detector and other psychological deception tests have proved their worth as a unique aid to investigation. However, in detection of deception interpretation of the Polygram has been under fire for its reliability and validity by the judiciary, labour unions and occasionally by the public as well. The basis of such criticism is the element of subjectivity in the interpretation of Polygram. This apart, the measurements of the physiological changes upon which the detection of deception tests are based still have not gained sufficient scientific recognition from physiologists and psychologists. Other adverse views are that the polygraph is:

- Not sufficiently accurate,
- Not reliable,
- Misused, and
- Humiliating and degrading for the person taking the test.

To rebut such criticism, the experts observe that a qualified and experienced polygraph examiner, by taking into account the specific deception criteria, can easily eliminate the subjective element from the interpretations.

The claims of the experts have been demonstrated experimentally where the objectives were to determine whether or not the professional polygraph examiners, working independently of each other, are able to detect deception successfully from the analysis of polygraphs only.

The examiners were given polygraph charts pertaining to actual field cases only. No other factual data with regard to the polygraph charts such as history of the case, test questions, subject's behaviour, etc. were supplied to the examiners. In three experiments, accuracy in judgment was reported as 75%, 87.8% and 86% respectively. If the examiners had access to the background information of the case, test questions and behaviour of the subject, the accuracy percentage would have been even higher. (CH)

Another objection against the use of polygraph is that inflated blood pressure cuff is inconvenient, painful and a psychological torture. The objection, however, is not legitimate. *Firstly*, the duration of the lie-detection test is very short, approximately 4 to 5 minutes, during which the inflated cuff certainly would cause no extensive physical pain. *Secondly*, if a slight discomfort for a few minutes can yield success in garnering the truth, the effort and method is far better than the prolonged interrogation the subject may otherwise have to bear. Lastly, the psychological feeling of torture is eliminated during the pre-interrogation interview with the subject. The inconvenience due to the cuff can be explained to him at that time. Further, the cuff has since been modified. It is no longer painful.

All said and done, the lie-detector is, for the detection of deception, an effective and valuable weapon, indispensable aid in the investigation of crime.

31.8 LEGAL STATUS

Largely, lie-detector evidence has limited judicial recognition. In a few courts of USA, polygraph test results have been recognised for their value as an aid to investigation and in some cases, the expert evidence relating to polygraph has been accepted. The experts in areas like fingerprints; firearms identification questioned documents have been widely acclaimed. But the polygraph experts have not received acceptance and recognition from the court. It is unfortunate when the polygraphists have established 95 to 98% accuracy of the lie-detector in detecting deception or the truthfulness of the subjects in criminal investigations. Based on relevant scientific data on the lie detector, it is strongly felt the courts should accept deception test results because it can furnish an effective method and technique for the exposure of deception in a subject. Since polygraph interrogation is the best available method to detect deception, the time has come for the courts to admit polygraph evidence.

The Chicago Bar Association Committee of Criminal Law undertook a study on the polygraph and its role in the administration of criminal justice. The committee concluded as follows:

- Polygraph has a place in the detection of crime because of the psychological effect on persons, who are in fact guilty of the crime.
- There may be 5–30 % errors in the test results, depending upon the ability of the examiner and other factors.
- Unqualified operators could cause unnecessary injury to innocent persons.
- Refusal to take a polygraph test should have no bearing on the presumption of innocence.
- The polygraph is not a substitute for the competent detection and investigation of crime.
- Due to the fallibility of the results of the polygraph examination, it should not be admitted as evidence in court cases.

The present position regarding the acceptability of lie detection test results is that in some of the courts of the USA it has been accepted as legal evidence. There are instances where the courts have recognised and utilised the polygraph test to base decisions. In USA, out of 23 States, 11 have enacted legislation to create a licensing authority for polygraphists to conduct

a certain specific type of polygraph examination, like cases of disputed paternity. In remaining 12 States, no such legislation has yet been enacted. The only other countries where polygraph has been put to extensive use in the criminal justice system are Japan and Israel. The legal status here is no different from that in the USA. In Japan, some of the courts have accepted the polygraph test results.

The use of lie detector in Canada or European countries, e.g., the U.K., France, and Germany and so on, is not extensive. Nevertheless, it is on the increase.

In India, Central Forensic Science Laboratory, Central Bureau of Investigation, New Delhi, was the first laboratory to create Lie Detection Division in 1972. The laboratory has examined more than nine thousand subjects. In fact, they are not able to provide examination facilities to those who requisition the same. Some other laboratories have also come up in other states including Gujarat, Maharashtra, Madhya Pradesh, and Karnataka. which are now providing the facility of polygraph for crime investigation purposes. A number of other institutions are also introducing the facility.

The polygraph test results do not appear to have been utilised in the courts extensively. However, there is no law, which forbids the use of lie detector in criminal investigations. In fact section 45 of the Indian Evidence Act is wide enough to accept the polygraph evidence. Supreme Court has allowed the uses of polygraph in police investigation *vide* their 2010 judgment in *Mst. Selvi v State of Karnataka*[6] though it has prohibited its use as evidence in the courts. They have placed a rider that the subject must give his informed consent before a magistrate prior to administration of the test. The same judgment has given the same rulings relating to other Forensic psychology branches like narco-analysis and brain profiling. In fact, consent of the subject was being taken even before the judgment.

The lie detectors are in fact providing useful assistance in criminal investigations in thousands of cases.

31.9 RECENT ADVANCES

The main innovation in the traditional polygraph has been the induction of computer to record and analyse the physiological responses and data, though some innovations in the input devices to increase the number of recording, to decrease the discomfort and to reduce the time for the examination have also come up.

Kircher and Yanka did the pioneer work to produce computer assisted polygraph system. They also developed the algorithm for fieldwork. Now instruments have come up with software, which sample, process and evaluate the data automatically with the help of the algorithm, for diagnostic purposes.

Computerised polygraph test has the following advantages:

1. Operational training need less time
2. It provides better interpretable data.
3. It does not need frequent calibrations; as in traditional polygraphs.
4. Data can be stored and printed.
5. Physiological signals analog can be digitized and algorithm can be developed.

6. *Mst. Selvi v State of Karnataka,* AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

31.9.1 New Input Devices

Electroencephalograph is a new device as far as PDD is concerned. It records the cognitive processes. It utilises the Event Related Brain Potential (ERP). For example, if the weapon of offence is shown to the subject and if he happens to be the culprit, he will recognise the weapon and EEG trace will show change in the wave pattern. The mode of recording and identifying the culprit's ERP is called brain Printing or Brain Fingerprinting on the pattern of DNA fingerprinting. Additional research is needed to make the technique more useful, in spite of the claims of 100% accuracy by some of its protagonist.

31.9.2 Non-Invasive Sensors/Transducers

The important non-invasive cardiovascular device is Finapres, which replaces blood pressure cuffs. Finapres is a transducer, applied to a finger, which responds to blood volume changes, which are recorded by the computer to give systolic and diastolic pressures and heart beat rate.

Likewise, voice response of answers "yes" or "no" to question put to subject is also being examined through voice spectrum analysis software. This examination is different from the analysis through Psychological Stress Elevator (PSE), which analyse subsonic laryngeal micro tremors for stress.

The main thrust is to develop additional software to analyse the PDD data. It is hoped that better software will improve the PDD data evaluation in the coming times.

An instrument utilising the neurosciences named ARIS (Automatic Response Indicator System) has also come up. It utilises homeostatic communication of the brain with the outer brain parts. It is believed that the Central Nervous System (CNS) controls the working of the outer parts. The control is disturbed by deception. The instrument (patented) measures the disturbance. ARIS algorithm consists of blood pressure, respiration, electro-dermal response, movement and EEG.

31.11 CASE LAW

31.11.1 Evidence Inadmissible[7]

1. The legal questions in this batch of criminal appeals relate to the involuntary administration of certain scientific techniques, namely **narcoanalysis, polygraph examination and the Brain Electrical Activation Profile (BEAP) tes**t for the purpose of improving investigation efforts in criminal cases.

This issue has received considerable attention since it involves tensions between the desirability of efficient investigation and the preservation of individual liberties. Ordinarily the judicial task is that of evaluating the rival contentions in order to arrive at a sound conclusion. However, the present case is not an ordinary dispute between private parties. It raises pertinent questions about the meaning and scope of fundamental rights which are available to all

7. *Mst. Selvi v State of Karnataka,* AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

citizens. Therefore, we must examine the implications of permitting the use of the impugned techniques in a variety of settings.

2. Objections have been raised in respect of instances where individuals who are the accused, suspects or witnesses in an investigation have been subjected to these tests without their consent. Such measures have been defended by citing the importance of extracting information which could help the investigating agencies to prevent criminal activities in the future as well as in circumstances where it is difficult to gather evidence through ordinary means. In some of the impugned judgments, reliance has been placed on certain provisions of the Code of Criminal Procedure, 1973 and the Indian Evidence Act, 1872 to refer back to the responsibilities placed on citizens to fully co-operate with investigation agencies. It has also been urged that administering these *techniques* does not cause any bodily harm and that the extracted information will be used only for strengthening investigation efforts and will not be admitted as evidence during the trial stage. The assertion is that improvements in fact-finding during the investigation stage will consequently help to increase the rate of prosecution as well as the rate of acquittal. Yet another line of reasoning is that these scientific techniques are a softer alternative to the regrettable and allegedly widespread use of 'third degree methods' by investigators.

3. The involuntary administration of the impugned techniques prompts questions about the protective scope of the 'right against self-incrimination' which finds place in Article 20(3) of our Constitution. In one of the impugned judgments, it has been held that the information extracted through methods such as 'polygraph examination' and the 'Brain Electrical Activation Profile (BEAP) test' cannot be equated with 'testimonial compulsion' because the test subject is not required to give verbal answers, thereby falling outside the protective scope of Article 20(3). It was further ruled that the verbal revelations made during a narcoanalysis test do not attract the bar of article 20(3) since the inculpatory or exculpatory nature of these revelations is not known at the time of conducting the test. To address these questions among others, it is necessary to inquire into the historical origins and rationale behind the 'right against self-incrimination'. The principal questions are whether this right extends to the investigation stage and whether the test results are of a 'testimonial' character, thereby attracting the protection of article 20(3). Furthermore, we must examine whether relying on the test results or materials discovered with the help of the same creates a reasonable likelihood of incrimination for the test subject.

4. We must also deal with arguments invoking the guarantee of 'substantive due process' which is part and parcel of the idea of 'personal liberty' protected by article 21 of the Constitution. The first question in this regard is whether the provisions in the Code of Criminal Procedure, 1973 that provide for 'medical examination' during the course of an investigation can be read expansively to include the impugned techniques, even though the latter is not explicitly enumerated. To answer this question, it will be necessary to discuss the principles governing the interpretation of statutes in light of scientific advancements. Questions have also been raised with respect to the professional ethics of medical personnel involved in the administration of these techniques. Furthermore, article 21 has been judicially expanded to include a 'right against cruel, inhuman or degrading treatment', which requires us to determine whether the involuntary administration of the impugned techniques violates this right whose scope corresponds with evolving international human rights norms. We must also consider contentions that have invoked the test subject's 'right to privacy', both in a physical and mental sense.

5. The scientific validity of the impugned techniques has been questioned and it is argued that their results are not entirely reliable. For instance, the narcoanalysis technique involves the intravenous administration of sodium pentothal, a drug which lowers inhibitions on part of the subject and induces the person to talk freely. However, empirical studies suggest

that drug-induced revelations need not necessarily be true. Polygraph examination and the BEAP test are methods which serve the respective purposes of lie-detection and gauging the subject's familiarity with information related to the crime. These techniques are essentially confirmatory in nature, wherein inferences are drawn from the physiological responses of the subject. However, the reliability of these methods has been repeatedly questioned in empirical studies. In the context of criminal cases, the reliability of scientific evidence bears a causal link with several dimensions of the right to a fair trial such as the requisite standard of proving guilt beyond reasonable doubt and the right of the accused to present a defence. We must be mindful of the fact that these requirements have long been recognised as components of 'personal liberty' under article 21 of the Constitution. Hence, it will be instructive to gather some insights about the admissibility of scientific evidence.

9. The origins of polygraph examination have been traced back to the efforts of Lombroso, a criminologist who experimented with a machine that measured blood pressure and pulse to assess the honesty of persons suspected of criminal conduct. His device was called a hydrosphygmograph. A similar device was used by psychologist William Marston during World War I in espionage cases, which proved to be a precursor to its use in the criminal justice system. In 1921, John Larson incorporated the measurement of respiration rate and by 1939 Leonard Keeler added skin conductance and an amplifier to the parameters examined by a polygraph machine.

10. The theory behind polygraph tests is that when a subject is lying in response to a question, he/she will produce physiological responses that are different from those that arise in the normal course. During the polygraph examination, several instruments are attached to the subject for measuring and recording the physiological responses. The examiner then reads these results, analyzes them and proceeds to gauge the credibility of the subject's answers. Instruments such as cardiographs, pneumographs, cardio-cuffs and sensitive electrodes are used in the course of polygraph examinations. They measure changes in aspects such as respiration, blood pressure, blood flow, pulse and galvanic skin resistance. The truthfulness or falsity on part of the subject is assessed by relying on the records of the physiological responses.[8]

11. There are three prominent polygraph examination techniques:

(i) The relevant-irrelevant (R-I) technique

(ii) The control question (CQ) technique

(iii) Directed Lie-Control (DLC) technique.

Each of these techniques includes a pre-test interview during which the subject is acquainted with the test procedure and the examiner gathers the information which is needed to finalize the questions that are to be asked. An important objective of this exercise is to mitigate the possibility of a feeling of surprise on part of the subject which could be triggered by unexpected questions. This is significant because an expression of surprise could be mistaken for physiological responses that are similar to those associated with deception. [Refer: David Gallai, '*Polygraph evidence in federal courts: Should it be admissible?*' 36 American Criminal Law Review 87-116 (Winter 1999) at p 91]. Needless to say, the polygraph examiner should be familiar with the details of the ongoing investigation. To meet this end the investigators are required to share copies of documents such as the First Information Report (FIR), Medico-Legal Reports (MLR) and Post-Mortem Reports (PMR) depending on the nature of the facts being investigated.

8. "Laboratory Procedure Manual: Polygraph Examination," Directorate of Forensic Science, Ministry of Home Affairs, Government of India, New Delhi, 2005.

12. The control-question (CQ) technique is the most commonly used one and its procedure as well as scoring system has been described in the materials submitted on behalf of CBI. The test consists of control questions and relevant questions. The control questions are irrelevant to the facts being investigated but they are intended to provoke distinct physiological responses, as well as false denials. These responses are compared with the responses triggered by the relevant questions. Theoretically, a truthful subject will show greater physiological responses to the control questions which he/she has reluctantly answered falsely, than to the relevant questions, which the subject can easily answer truthfully. Conversely, a deceptive subject will show greater physiological responses while giving false answers to relevant questions in comparison to the responses triggered by false answers to control questions. In other words, a guilty subject is more likely to be concerned with lying about the relevant facts as opposed to lying about other facts in general. An innocent subject will have no trouble in truthfully answering the relevant questions but will have trouble in giving false answers to control questions. The scoring of the tests is done by assigning a numerical value, positive or negative, to each response given by the subject. After accounting for all the numbers, the result is compared to a standard numerical value to indicate the overall level of deception. The net conclusion may indicate truth, deception or uncertainty.

13. The use of polygraph examinations in the criminal justice system has been contentious. In this case, we are mainly considered with situations when investigators seek reliance on these tests to detect deception or to verify the truth of previous testimonies. Furthermore, litigation related to polygraph tests has also involved situations where suspects and defendants in criminal cases have sought reliance on them to demonstrate their innocence. It is also conceivable that witnesses can be compelled to undergo polygraph tests in order to test the credibility of their testimonies or to question their mental capacity or to even attack their character.

14. Another controversial use of polygraph tests has been on victims of sexual offences for testing the veracity of their allegations. While several states in the USA have enacted provisions to prohibit such use, the text of the *Laboratory Procedure Manual for Polygraph Examination* [supra.] indicates that this is an acceptable use. In this regard, para 3.4(v) of the said Manual reads as follows:

> *(v) In cases of alleged sex offences such as intercourse with a female child, forcible rape, indecent liberties or perversion, it is important that the victim, as well as the accused, be made available for interview and polygraph examination. It is essential that the polygraph examiner get a first-hand detailed statement from the victim, and the interview of the victim precedes that of the suspect or witnesses. ...*

[The following article includes a table which lists out the statutorily permissible uses of polygraph examination in the different state jurisdictions of the United States of America.[9]

> *15. The propriety of compelling the victims of sexual offences to undergo a polygraph examination certainly merits consideration in the present case. It must also be noted that in some jurisdictions polygraph tests have been permitted for the purpose of screening public employees, both at the stage of the recruitment and at regular intervals during the service-period. In the USA, the widespread acceptance of polygraph tests for checking the antecedents and monitoring the conduct of public employees has encouraged private employers to resort to the same. In fact the Employee Polygraph Protection Act, 1998 was designed to restrict their use for employee screening. This development must be noted because the unqualified acceptance of 'Lie-detector tests' in India's criminal justice system could have the unintended consequence of encouraging their use by private parties.*

16. Polygraph tests have several limitations and therefore a margin for errors. The premise behind these tests is questionable because the measured changes in physiological responses are not necessarily triggered by lying or deception. Instead, they could be triggered by nervousness,

9. Henry T. Greely and Judy Illes, "Neuroscience based lie-detection: The urgent need for regulation," 33 American Journal of Law and Medicine, 2007, pp 377–421.

anxiety, fear, confusion or other emotions. Furthermore, the physical conditions in the polygraph examination room can also create distortions in the recorded responses. The test is best administered in comfortable surroundings where there are no potential distractions for the subject and complete privacy is maintained. The mental state of the subject is also vital since a person in a state of depression or hyperactivity is likely to offer highly disparate physiological responses which could mislead the examiner. In some cases the subject may have suffered from loss of memory in the intervening time-period between the relevant act and the conduct of the test. When the subject does not remember the facts in question, there will be no self-awareness of truth or deception and hence the recording of the physiological responses will not be helpful. Errors may also result from 'memory-hardening', *i.e.*, a process by which the subject has created and consolidated false memories about a particular incident. This commonly occurs in respect of recollections of traumatic events and the subject may not be aware of the fact that he/she is lying.

17. The errors associated with polygraph tests are broadly grouped into two categories, *i.e.*, 'false positives' and 'false negatives'. A 'false positive' occurs when the results indicate that a person has been deceitful even though he/she answered truthfully. Conversely, a 'false negative' occurs when a set of deceptive responses is reported as truthful. On account of such inherent complexities, the qualifications and competence of the polygraph examiner are of the utmost importance. The examiner needs to be thorough in preparing the questionnaire and must also have the expertise to account for extraneous conditions that could lead to erroneous inferences.

18. However, the biggest concern about polygraph tests is that an examiner may not be able to recognise deliberate attempts on part of the subject to manipulate the test results. Such 'countermeasures' are techniques which are deliberately used by the subject to create certain physiological responses in order to deceive the examiner. The intention is that by deliberately enhancing one's reaction to the control questions, the examiner will incorrectly score the test in favour of truthfulness rather than deception. The most commonly used 'countermeasures' are those of creating a false sense of mental anxiety and stress at the time of the interview, so that the responses triggered by lying cannot be readily distinguished.

19. Since polygraph tests have come to be widely relied upon for employee screening in the USA, the US Department of Energy had requested the National Research Council of the National Academies (NRC) to review their use for different purposes. The following conclusion was stated in its report, *i.e.* The Polygraph and Lie-Detection: Committee to Review the scientific evidence on the Polygraph (Washington D.C.: National Academies Press, 2003) at pp 212-213:

> **Polygraph Accuracy:** Almost a century of research in scientific psychology and physiology provides little basis for the expectation that a polygraph test could have extremely high accuracy. The physiological responses measured by the polygraph are not uniquely related to deception. That is, the responses measured by the polygraph do not all reflect a single underlying process: a variety of psychological and physiological processes, including some that can be consciously controlled, can affect polygraph measures and test results. Moreover, most polygraph testing procedures allow for uncontrolled variation in test administration (*e.g.*, creation of the emotional climate, selecting questions) that can be expected to result in variations in accuracy and that limit the level of accuracy that can be consistently achieved.

Theoretical Basis: The theoretical rationale for the polygraph is quite weak, especially in terms of differential fear, arousal, or other emotional states that are triggered in response to relevant or comparison questions. We have not found any serious effort at construct validation of polygraph testing.

Research Progress: Research on the polygraph has not progressed over time in the manner of a typical scientific field. It has not accumulated knowledge or strengthened its scientific underpinnings in any significant manner. Polygraph research has proceeded in relative isolation

from related fields of basic science and has benefited little from conceptual, theoretical, and technological advances in those fields that are relevant to the psycho-physiological detection of deception.

Future Potential: The inherent ambiguity of the physiological measures used in the polygraph suggests that further investments in improving polygraph technique and interpretation will bring only modest improvements in accuracy."

20. A Working Party of the British Psychological Society (BPS) also came to a similar conclusion in a study published in 2004. The key finding is reproduced below, [Cited from: A review of the current scientific status and fields of application of polygraph deception detection – Final Report (6 October, 2004) from The British Psychological Society (BPS) Working Party at p. 10]:

"A polygraph is sometimes called a lie detector, but this term is misleading. A polygraph does not detect lies, but only arousal which is assumed to accompany telling a lie. Polygraph examiners have no other option than to measure deception in such an indirect way, as a pattern of physiological activity directly related to lyin g does not exist (Saxe, 1991). Three of the four most popular lie detection procedures using the polygraph (Relevant/Irrelevant Test, Control Question Test and Directed Lie Test, ...) are built upon the premise that, while answering so-called 'relevant' questions, liars will be more aroused than while answering so-called 'control' questions, due to a fear of detection (fear of getting caught lying). This premise is somewhat naive as truth tellers may also be more aroused when answering the relevant questions, particularly: (i) when these relevant questions are emotion evoking questions (*e.g.,* when an innocent man, suspected of murdering his beloved wife, is asked questions about his wife in a polygraph test, the memory of his late wife might re-awaken his strong feelings about her); and (ii) when the innocent examinee experiences fear, which may occur, for example, when the person is afraid that his or her honest answers will not be believed by the polygraph examiner. The other popular test (Guilty Knowledge Test,...) is built upon the premise that guilty examinees will be more aroused concerning certain information due to different orienting reactions, that is, they will show enhanced orienting responses when recognising crucial details of a crime.

This premise has strong support in psychophysiological research (Fiedler, Schmidt & Stahl, 2002)."

31.12 CONCLUSION

In our considered opinion, the compulsory administration of the impugned techniques violates the 'right against self-incrimination'. This is because the underlying rationale of the said right is to ensure the reliability as well as voluntariness of statements that are admitted as evidence. This Court has recognised that the protective scope of Article 20(3) extends to the investigative stage in criminal cases and when read with section 161(2) of the Code of Criminal Procedure, 1973 it protects accused persons, suspects as well as witnesses who are examined during an investigation. The test results cannot be admitted in evidence if they have been obtained through the use of compulsion.

Article 20(3) protects an individual's choice between speaking and remaining silent, irrespective of whether the subsequent testimony proves to be inculpatory or exculpatory. Article 20(3) aims to prevent the forcible 'conveyance of personal knowledge that is relevant to the facts in issue'. The results obtained from each of the impugned tests bear a 'testimonial' character and they cannot be categorised as material evidence.

We are also of the view that forcing an individual to undergo any of the impugned techniques violates the standard of 'substantive due process' which is required for restraining personal liberty. Such a violation will occur irrespective of whether these techniques are forcibly administered during

the course of an investigation or for any other purpose since the test results could also expose a person to adverse consequences of a non-penal nature. The impugned techniques cannot be read into the statutory provisions which enable medical examination during investigation in criminal cases, *i.e.*, the *Explanation* to sections 53, 53A and 54 of the Code of Criminal Procedure, 1973. Such an expansive interpretation is not feasible in light of the rule of '*ejusdem generis*' and the considerations which govern the interpretation of statutes in relation to scientific advancements. We have also elaborated how the compulsory administration of any of these techniques is an unjustified intrusion into the mental privacy of an individual. It would also amount to 'cruel, inhuman or degrading treatment' with regard to the language of evolving international human rights norms. Furthermore, placing reliance on the results gathered from these techniques comes into conflict with the 'right to fair trial'. Invocations of a compelling public interest cannot justify the dilution of constitutional rights such as the 'right against self-incrimination'.

In light of these conclusions, we hold that no individual should be forcibly subjected to any of the techniques in question, whether in the context of investigation in criminal cases or otherwise. Doing so would amount to an unwarranted intrusion into personal liberty. However, we do leave room for the voluntary administration of the impugned techniques in the context of criminal justice, provided that certain safeguards are in place. Even when the subject has given consent to undergo any of these tests, the test results by themselves cannot be admitted as evidence because the subject does not exercise conscious control over the responses during the administration of the test. However, any information or material that is subsequently discovered with the help of voluntary administered test results can be admitted, in accordance with section 27 of the Evidence Act, 1872.

The National Human Rights Commission had published 'Guidelines for the Administration of Polygraph Test (Lie Detector Test) on an Accused' in 2000. These guidelines should be strictly adhered to and similar safeguards should be adopted for conducting the 'Narcoanalysis technique' and the 'Brain Electrical Activation Profile' test. The text of these guidelines has been reproduced below:

(i) No Lie Detector Tests should be administered except on the basis of the consent of the accused. An option should be given to the accused whether he wishes to avail such test.

(ii) If the accused volunteers for a Lie Detector Test, he should be given access to a lawyer and the physical, emotional and legal implication of such a test should be explained to him by the police and his lawyer.

(iii) The consent should be recorded before a Judicial Magistrate.

(iv) During the hearing before the Magistrate, the person alleged to have agreed should be duly represented by a lawyer.

(v) At the hearing, the person in question should also be told in clear terms that the statement that is made shall not be a 'confessional' statement to the Magistrate but will have the status of a statement made to the police.

(vi) The Magistrate shall consider all factors relating to the detention including the length of detention and the nature of the interrogation.

(vii) The actual recording of the Lie Detector Test shall be done by an independent agency (such as a hospital) and conducted in the presence of a lawyer.

(viii) A full medical and factual narration of the manner of the information received must be taken on record.

31.12.1 Evidence Admissible[10]

> Insofar as the Polygraph [Lie Detection] Test which was conducted on A-2 is concerned, Mr. Sushil Kumar submits that since polygraph evidence is not subject of expert evidence as per section 45 of Evidence Act being a science in mystique, it could at best be used as an aid to investigation and not as evidence. In support of his submission, he has relied on *Romeo Phillion and Her Majesty The Queen,* (1978) 1 SCR 18 and *R. v Beland*, (1987) 2 SCR 398, which are decisions rendered by the Canadian Supreme Court, and on *Mallard v Queen*, 2003 WASCA 296, a decision of the Australian Supreme Court. Mr. Tulsi, on the other hand, submits that the result of Polygraph Test can be used against the accused. As there are other materials sufficient for upholding conviction of A-2, we refrain ourselves from going into the question of admissibility or otherwise of the result of Polygraph Test in the present case.

31.12.2 Lie Detector Evidence[11]

Another breakthrough has been made in the acceptance of polygraph (lie detector) evidence by courts. The Wisconsin Supreme Court, in a landmark decision on 4 April 1974, reversed its 40-year-old rule and decided that lie detector evidence was admissible in a criminal case. Polygraph evidence now has reached the same level of scientific reliability as evidence produced by the science of fingerprints, ballistics, voice-prints, and electroencephalographs, according to the court. This decision reverses the former rule in *Wisconsin, State v Bohner,*[12] which was first set out in the Federal case *Frye v United States.*[13]

In the *Stanislawski* case, an appeal was taken from a jury conviction for rape. A polygraph test had been administered both to S., and to the complaining witness by the police, but due to the law in Wisconsin at the time, results of the tests could not be introduced in court. (The tests showed the defendant to be telling the truth and the witness to be lying.) In overturning the conviction of S., the Supreme Court stated:

> Under the test of general acceptance of scientific standing in the field in which it belongs, there has been a marked change in acceptance of polygraph testing in the forty-plus years since *Bohner* and 50-plus years since *Frye*. There is a widespread use of polygraph testing by industries, banks, insurance companies, police departments, and governments, including the armed forces. The business of private polygraph examiners increased eight to ten times in the decade 1950-1960.
>
> The court further found:
>
> .....polygraph tests have moved..... to such degree of standing and scientific recognition that unconditional rejection of expert testimony based on polygraph testing is no longer indicated.

The new rules and qualifications of admissibility were adopted from a case decided by the Arizona Supreme Court in *State v Valdez.*[14] The results of a lie detector examination were admissible for two purposes:

> .....to corroborate other evidence of a defendant's participation in the crime charged" and, "If he takes the stand such evidence is admissible to corroborate or impeach his own testimony.

---

10. *Ram Singh . Sonia,* Appeal (Crl) 895 of 2005 [Bench: B.N. Agrawal & P.P. Naolekar], decided on 15 February 2007.
11. King, D.P. 1974, Case Notes, USA Criminologist. 9 (34), 39; *State v Stanislaw Ski,* 62 Wis 2d 730 (1974), Wisconsin Supreme Court.
12. 210 Wis 651 (1933)
13. (1923) 54 App DC 46 : 293 F 1013 (DC Cir 1923).
14. 91 Ariz 274 (1962).

The court set up four conditions which must be met before such testimony is admitted:

1. That the district attorney, defendant and his counsel all sign a written stipulation providing for defendant's submission to the test and the subsequent admission at trial of the graphs, and the examiner's opinion thereon on behalf of either defendant or the State.
2. That notwithstanding the stipulation to admissibility of the test results is subject to the discretion of the trial court, *i.e.,* if the trial judge is not convinced that the examiner is qualified or that the test was not conducted under proper conditions he may refuse to accept such evidence.
3. That if the graphs and examiner's opinion are offered in evidence the opposing party shall have the right to cross-examine the examiner respecting:
   (a) the examiner's qualifications and training;
   (b) the conditions under which the test was administered;
   (c) the limitations of and possibilities for error in the technique of polygraph interrogation; and
   (d) at the discretion of the trial court, any other matter deemed pertinent to the enquiry.
4. That if such evidence is admitted the trial judge should instruct the jury that the examiner's testimony does not tend to prove or disprove any element of the crime with which a defendant is charged but at most tends only to indicate whether at the time of the examination defendant was telling the truth. Further, the jury members should be instructed that it is for them to determine what corroborative weight and effect such testimony should be given.

The Wisconsin decision was the further step in the increasing acceptability of polygraph evidence in U.S. Courts.

CHAPTER 32

NARCO-ANALYSIS INTERROGATION

(TRUTH SERUM TEST)

SYNOPSIS

32.1 General 1561
32.1.1 Definition 1561
32.1.2 Basis 1562
32.1.3 Presumptions 1562
32.2 Process 1563
32.2.1 Narco-analysis Interrogation 1563
32.2.2 Narco-analysis Room 1563
32.2.3 The Drug 1564
32.2.4 The Subject 1564
32.2.5 The Examiner 1564
32.2.6 Sources of Errors 1564
32.2.7 Laboratories 1565
32.3 Importance 1565

32.8 Additional Readings 1573
32.9 Case Law 1574
32.9.1 Supreme Court on Narco-analysis in 21st Century 1574
32.9.2 Narco-analysis Technique 1575

32.1 GENERAL

32.1.1 Definition

Narco-analysis is a chemo-physiological test administered to a crime suspect to extract truth when he is not willing to tell the truth and tell lies in normal interrogation. It is an interrogation of a suspect, after giving him an injection, intravenously, of a suitable dose of a psychoactive (hypnotic) drug — a barbiturate most of the time. Usually the barbiturate is **Sodium thiopentothal**[1] or **Sodium Amytal**[2] (**Amobarbital**). The injection is administered under controlled conditions to reduce or eliminate the reasoning power of the subject without affecting his memory. Diazepam compound notably benzodiazepine is considered safer. However, in India sodium pentothal is the drug used generally. The narcotic affects adversely that part of the brain of the subject, which discriminates between what is good or bad for him; according to his own values and thinking. In short, the drug suppresses his thinking and reasoning powers.

The narcotic used for the purpose is given the fancy name of Truth Serum by the story writers and media persons to attract attention. They also name the process as Truth Serum Test. In India, the word is "Narco".

1. It is the most common barbiturate used in narco-analysis. It is ultra-short acting barbiturate and the effects last only for a few minutes. It causes a state of semi-consciousness in the subject.
2. The barbiturate makes the person more talkative. He may thus reveal truth.

32.1.2 Basis

The fact that certain materials affect the brain has been known since ancient times. Alcohol[3], opium, cannabis and some other substances have been used or misused from prehistoric times almost all over the world. The use of barbiturate in controlling brain functions, under controlled conditions, is an extension of the process in a purpose-specific mode for interrogating refractory subjects. Formerly, the people did not understand the mechanism of the action of these drugs on man. Now they know how they work.

The brain affecting chemicals enter the brain through circulating blood. They affect certain parts of the brain preferentially. Researchers have found which drug effect which part and with what results. For interrogation, they found drugs which suppress the reasoning power but not the memory or speech equally. They found that Sodium Pentothal is, so far, the drug of choice for the purpose. However, the research is going on and it is hoped that still better drugs may come up in the near future. Or, some newer techniques of interrogation may come up and make the Narco-analysis techniques redundant.

32.1.3 Presumptions

Narco-analysis is based upon certain presumptions. These presumptions do not necessarily hold good in all cases. Where they hold well, the analyst gets useful results, but if they fail, not only the results are useless, but they are sometimes harmful. They mislead investigations.

The common presumptions about Narco-analysis are:

1. The hypnotic or other drug injected in the body suppresses the reasoning power of the subject to an extent that his answers are from memory without any effort to appraise. Rationalise or suppress the truth. It is not so always.

The human body including the brain is such that it varies from person to person. The dose administered to a person may or may not suppress his reasoning power and other faculties.

> *A very senior officer, who was a teetotaler, once related a personal experience. His friends asked him to drink half a bottle of whisky (about 375 ml.) and drive a vehicle for about 25 kilometres. He did it! (CH)*

Or, it may suppress the power only partially and the subject is able to fib; to save his skin, if he so desires. Clever criminals often pretend that they are in the 'desired' trance and mislead the examiner with a bundle of lies. The sub-presumptions are:

2. The subject has not mixed the truth about the event with his imagination, fantasies or other similar incidents.
3. He has not rationalised the events of the occurrence in his subconscious mind.
4. He is not influenced by the media versions or by the versions of his near and dear ones.
5. He is not under Conformational Syndrome.[4]
6. He has a sharp and long-lasting memory and can recall the events even under the influence of the drugs.
7. He tells lies to save himself when not drugged.
8. The dose of the hypnotic drug is adequate to numb his reasoning power and that the effect of the drug lasted for the whole interrogation interval. It may be mentioned

3. Police still use it on some subjects to make them more talkative and to reduce their inhibitions.
4. He is not conforming mechanically to what is put up to confirm.

that the drug commonly used in India (Sodium Pentothal) in an ultra-short acting drug and its effect lasts only for a few minutes. The examiner must complete the interrogation in that small interval.

9. The examiner is an unbiased competent expert and has framed non-suggestive questioned which can elicit the correct information which is not based on his suggestions.

The failure of one or more of these assumptions at times has created an ongoing controversy:

1. Is psychoanalysis scientific?
   - Are the findings, based upon recognised scientific principles?
   - Are the techniques recognised, evaluated and approved by the concerned scientific fraternity?
   - Have the tools and techniques been reviewed by senior scientists in the fields?
   - Are the margins of errors known? Have they been taken into consideration?
2. Is it another mode of Third Degree Methods or torture?
3. Should its findings be used as evidence in courts? Or, should they be used only in the investigation process.
4. Does it violate article 20(3)[5]: (No person can be compelled to be a witness against himself) of the constitution?

These controversies have adversely affected the utilisation of the Narco-analysis in the fight against crime. Half-baked courts' decisions have added fuel to the fire. It is true that Narco-analysis has lacunae. However, with more inputs in the form of research, they could be overcome and a state of workable trance can be obtained.

32.2 PROCESS

32.2.1 Narco-analysis Interrogation

As already seen Narco-analysis is an interrogation technique under modified mental conditions of the subject, to prevent him from telling lies. The preliminaries, prior to the administering Narco-analysis test, are:

- Permission for the test is obtained from a magistrate.
- Consent of the subject is recorded to satisfy the need of article 20(3) of the Constitution and that of Supreme Court directions that the subject is not being compelled to undergo the test.
- Fitness of the subject, to undergo the test, is checked by a general physician. He gives a certificate thereof.

32.2.2 Narco-analysis Room

The test is carried out in an operation theatre, ordinarily, so that in case need arises medical assistance can be provided to the subject. A general physician keeps a watch on the subject and an anaesthetist who administers the drug are the only persons present in the room in addition to the narco-analyst. The room is free from noise and other disturbances.

5. Article 20(3): "No person accused of an offence can be compelled to be a witness against himself." Administering hypnotic is not compelling the accused to be a witness against himself. Refer to full Bench of the Supreme Court in *State of Mumbai v Kathi Kal*u, (1961) 2 Cr LJ 856 (SC).

32.2.3 The Drug

The drug for Narco-analysis interrogation is usually Sodium Pentothal in the form of 0.01 per cent solution in pure water. An anaesthetist injects it intravenously, in a vein on the back of the hand, slowly. The dose is usually 0.25 to 0.50 gram. In some cases, the dose may be even one gram. The anaesthetist determines the quantity of the dose to ensure creation of a trance-like state in the subject. He monitors and modulates the degree of unconsciousness during the interrogation.

Dose strength is the most critical part of the test. Excess dose can kill the subject and a lighter dose will not create the desired semi-conscious state. In such a case, the subject may pretend that he is in trance, without being so. He then gives answers to mislead the investigator, explicate himself and may implicate some other person(s). If the desired trance is achieved, he answers questions without deliberations. These answers are believed to be truthful.

The drug dose varies from person to person and depends upon his health, will power and his attitude towards life in general and to the test in particular. The anaesthetist takes age, weight and general built into consideration while determining the dose for a particular subject.

32.2.4 The Subject

The subject has to be in good mental and physical health. A general medical practitioner certifies the same after carrying out medical examination and bio-medical test if necessary. He should be free from heart diseases, diabetes, blood pressure, liver, and kidney problems. In case of women subjects they should not be pregnant or lactating mothers at the time of Narco-analysis interrogation.

The subject must not be a drug addict or on barbiturates therapy. The subject should not be suffering from depression.

The subject is acclimatised to the environment before he is given the test.

32.2.5 The Examiner

The narco-analyst, a Forensic Psychologist, takes over the subject once semi-conscious state is achieved. The psychologist has already studied the circumstances of the case, obtained all the details of the investigative findings and knows the aim of interrogation. Further, the analyst, in an informal chat, familiarises the subject with the various aspects of the test prior to examination. In short, he removes the fears of the test of the subject.

He prepares a questionnaire beforehand to extract the desired meaningful information from the subject.

The anaesthetist and the psychologist (sometimes a psychiatrist also) work in the presence of the general physician who had certified the physical fitness of the subject not only to take the narco-analysis interrogation before starting the test but he, after the test also certifies that there is no adverse effect of the test on the subject.

Narco-analysis interrogation is teamwork. Usually, the team consists of three persons mentioned above: the medical professional, the anaesthetist and the forensic psychologist.

An imaging expert takes video and audio films of the process and he records the other details of the test. The film so prepared form part of the report submitted to the courts or sent to the requisitioning authorities.

32.2.6 Sources of Errors

In spite of the fact that the effect of drugs on the human brain is known from time immemorial, there is insufficient research on the process. There are deficiencies and pitfalls, real or imaginary, in Narco-analysis interrogation, including the following:

1. There is no sure test to indicate that the trance is real or fake.
2. There is no guarantee that the subject is not just accepting the suggestions of the examiner or telling what he has done or seen.
3. There is no surety that the subject is giving facts or mixing them with lies.
4. The subject may intermingle the present incident with some other incident.
5. There is no way to know if the subject is relating to non-existing imaginary incidents, which he believes to be true in a normal state of mind. The result of interrogation may be the outpourings of such events.
6. There is no statistical base for the validity of the test.
7. There is no general acceptance of narco-analysis.
8. The answers of the suspect may be the result of disorientation of the brain and interrogation results may be the outcome of some delusion, hallucinations, etc.
9. The subject may be suffering from hyper amnesia and give self-created details.
10. The subject, in normal interrogation, is told repeatedly: "**you have done it"**. In Narco-analysis interrogation, he remembers the statement and accepts it: "**I have done it"** though he may not have done it.
11. It is alleged that Narco-analysis interrogation suffers from Conformational Syndrome: the specialist gives what the investigators want. However, it is not so. Bangalore Laboratory results showed that narco-analysis interrogation, in about 25% cases the subjects were found innocent of the crimes they were accused of.

32.2.7 Laboratories

Two State Forensic Science Laboratories: one at Bengaluru (Bangalore) and the other at Ahmedabad have facilities to carry out narco-analysis interrogation in India. The former carries out the test at Victoria Hospital, Bengaluru. The reports of the Bengaluru Laboratory are highly encouraging. It reports a very high rate of success in the tests. About a thousand persons have already undergone Narco-analysis interrogation.

32.3 IMPORTANCE

Narco-analysis is an interrogation technique to get correct and truthful information from the subject who does not furnish correct information under normal interrogation.

32.3.1 Ned

There are many reasons for which he does not tell the truth including the following:

1. To avoid incrimination
2. Fear of reprisals from the adversely affected party
3. Nervous breakdown from the recall of the horrid incident

Two girls were walking at dusk in an unfrequented area in a small town, in UK. They were attacked by a person. He killed one and raped the second. The latter was shell-shocked, could not give the details of the culprit, and would go unconscious on questioning. She was put under hypnosis. She gave complete details.

The face of the culprit was reconstructed from the details she gave on interrogation under hypnosis. When the reconstructed sketch of the face was shown to her, she at once exclaimed that he was the culprit. (CH)

4. Mind going blank due to emotional shock

In such cases, the help of Forensic Psychology is indispensable. It may be hypnosis, narco-analysis or some other technique. The varied techniques have their own plus and minus points.

32.3.2 Applications

Narco-analysis is used in many crime situations including the following:

1. **Interrogation of spies**: spies are a special category of subjects, *via-a-vis* interrogation. They are specially trained foreign (government) agents sent to other countries to gather secret and classified information. Their training includes how to face (and counter) interrogation when they are caught. The training toughens them so much that most of the methods of interrogations fail. In such cases, Narco-analysis has given positive results.
2. **Interrogation of terrorists:** terrorists are another class of criminals who are highly motivated. They resist normal interrogations. The effective way to extract information from them is by putting them in trance and gets details about their past, present and also of future plans.
3. **Interrogation of revolutionaries:** revolutionaries are dedicated individuals. They are thoroughly brainwashed. Their usual interrogation often fails. Narco-analysis interrogation often provides the needed information to check their ongoing and future depredations and to know the details of the past attacks.
4. **Interrogation of religious and racial fanatics:** religious and racial fanatics are a species apart. They are under the hypnotic spell of wrong religious fervour. This spell is overcome through narco-analysis interrogation. The narco-analysts have used narco-analysis in some cases[6] in India, with success.
5. **Interrogation of psychopathic and schizophrenic criminal:** psychopathic and schizophrenic criminals sometimes appear on the horizon. They are also difficult subjects for interrogations. Schizophrenic criminals are especially so because of their secretive nature, careful planning and self-preservation instinct. Narco-analysis proves effective with them.

   The use of hypnotics to get detailed and correct information started with Psychopathic patients as part of their treatment procedure. It has since been used extensively to interrogate criminals. The use of the technique is now limited in psychiatric investigations for the treatment.
6. **Interrogation of scam scoundrels:** in the past one decade India has been flooded with scam scoundrels of all sorts. Scams are results of corrupt practices and give rise to black money and money laundering, etc. in addition to raining a host of other evils.

   The perpetrators (ministers, business tycoons, bureaucrats, organised crime syndicates, etc.) of the scams are powerful men with bags of money and lots of influence. They easily manipulate the normal investigative and interrogation process. Narco-analysis interrogation can help to get information from such persons.
7. **Interrogation of cybercriminals: t**he cybercrimes do not provide the usual evidence against the criminal. Interrogation plays an important role in collecting evidence. But the cyber criminals feel smug that they can get away with the hi-tech crime. Narco-analysis interrogation proves useful in many cybercrime investigations.

32.3.3 Investigative Help

Narco-analysis interrogation, under favourable conditions, can help the investigator in many ways, including finding answers to the following questions:

6. In Godhara Kand and Malegaon cases the investigation were facilitated by Narco-analysis.

1. Is the subject under scan a criminal; or an associate/sympathiser/member of a criminal gang? Or, is he an innocent person?
2. Is he a serial criminal? If so, where, when and how did he commit the crimes? What was the chronology of the serial crimes?
3. Who were/are the victims?
4. What was his role in the incident(s)?
5. What are the evidentiary clues he picked up or left at the crime scene?
6. How has he disposed off the body?
7. Where has he hidden the *corpus delicti*?
8. Who were his associates?
9. What were his motives for the crime(s)?
10. Is he a psychopath?

In short, Narco-analysis interrogation, under favourable conditions, can bring out the true confession from the culprit and extract information on most of the aspects of the crime, which he may not be able to get through normal interrogation.

32.4 SUCCESS STORIES

Narco-analysis interrogation is not used widely in the world. The main reason for the neglect is that the process has not received general acceptance, both from the legal community and the scientific fraternity. The subject has not been researched extensively. Consequently, lacunae and oddities exist, which need ironing out through extensive research.

Narco-analysis involves the human brain, which is highly complex. It is responsible for all the human activities: observations, storage, remembering and recall of the information, rationalisation, thinking and action, etc. All its processes are influenced by emotions, motives, needs, attitudes and of course by life experiences, education, association and environment. The results vary from man to man, time to time and from situation to situation.

Narco-analysis is based on the assumption that the process suppresses, through narcotics, most of the brain activities, leaving, ideally, only recall and speech power. The success to reach the ideal state of trance varies with subjects, with the specialist and with the nature of the incident and circumstances of the case. In India, Karnataka State Laboratory has carried out the maximum number of Narco-analysis interrogations. The laboratory has reported/claimed exceptional success (rate: > 90 %). They have interrogated hundreds of criminals with success. Some of the success stories, in India, are given here.

We have some success stories in narco-analysis:

32.4.1 Bombay Serial Blast, 1993

Abu Salem masterminded the Mumbai Serial Blasts, 1993. He was part of the gang of Don Dawood Ibrahim. He carried out murders, extortions and kidnapping on a large scale and was wanted in many cases. He has amassed property worth hundreds of crores of rupees. After his separation from Dawood, he had to run away from India and Dubai. Interpol arrested him and his wife, Monica Bedi, in Lisbon in 2002. Both were extradited to India in 2005 under certain conditions. He was convicted for Mumbai Serial Blast and lodged in high-security Arthur jail.

Narco-analysis interrogation was used to find details of the 1993 blast and other cases carried at the State FSL Bengaluru by a team of specialists, consisting of a medical doctor, an anaesthetist and a Forensic Psychologist. A lot of useful information could be elicited from him.

Fig. 32.1

Changing faces of Abu Salem, from a petty criminal to Don of Mumbai underworld

32.4.2 Stamp Paper Scam

Abdul Karim Telgi masterminded the commission of the greatest forgery of our times, money-wise and area of operation-wise, infamous as the Stamp Paper Scam. He was subjected to Narco-analysis interrogation in December 2003 in State FSL Bengaluru. Telgi provided a lot of information about his *modus operandi*, his associates and his sale network of fake stamps over various parts of the country which helped to unravel the *modus operandi* and the personalities involved. He accomplished the most profitable forgery, guzzling more than thirty thousand crores of rupees and ensnaring hundreds of persons to be involved in the magnum forgery.

Fig. 32.2

Abdul Karim Telgi, who masterminded the stamp paper scam

32.4.3 Nithari Serial Murders

In 2005 and 2006**,** serial murders took place in Nithari village near Noida, UP, in the house of Moninder Singh Pandher a transporter. Bodies or parts thereof of sixteen girls were recovered from a nearby drain. He and his servant, Surender Koli, both were accused, tried, convicted and sentenced to death, relating to four victims, by the trial judge[7] on 13 February 2009. The judge dubbed it as the

rarest of the rare cases.

7. The High Court, Allahabad, acquitted Pandher. He is still an accused in other cases.

In January 2015, Koli's death penalty was commuted to life imprisonment by the High Court. Koli has been confined in Dasna jail ever since his arrest in December 2006.

A Ghaziabad CBI court awarded death sentence to Nithari case convict Surinder Koli in the murder of a 14-year-old girl. This is the tenth death sentencing for Koli while hearing is still going on in six remaining cases.[8]

Fig. 32.3

Surender Koli, main accused in the Nithari serial murders gave extensive information on narcoanalysis interrogation

During an investigation of the serial murders, the two accused were subjected to Narco-analysis interrogation successfully in the Gujrat State FSL, at Gandhinagar. The interrogation gave useful information. The result of the test indicated that Koli had done the killings alone, by strangulating the victims. It was also revealed that after killing Koli would rape the victims, dismember them in his bathroom and then throw them in the drain.

He could give the names of most of the victims under the influence of the drug.

According to Koli, Pandher did not take part in the killings. The Narco-analysis interrogation of Pandher, however, found that he was a womaniser and under depression.

32.5 NARCO-ANALYSIS AS SCIENCE

Science has been defined as organised knowledge on any subject. It starts with an idea, often called a hypothesis. This hypothesis is then tested through experiments or studying natural phenomena. Observations are made. If the observations in a number of experiments or natural phenomena are in consonance with the conceived hypothesis, the hypothesis is dubbed as theory. The scientific fraternity explores the theory further. If most of them find the theory consistent, the theory is called law or principle, usually after general acceptance.

Let us apply the same criteria to Narco-analysis interrogation, to see if it is a science or not.

The psychiatrists discovered that hypnotics create a trance-like state in humans, long ago. They used them on their mental patients to understand their mental problems through hypnotics which created a semi-conscious state. Forensic Psychologist took the cue and started experimenting with barbiturates (hypnotics) to create the twilight state in untruthful subjects (mostly criminals, some frightened (liar) witnesses or victims). The experimental work, the observations and drawing of inferences about the hypnotics in this context are still going on to:

8. Times of India, 2 March 2019.

- Find better and better hypnotics.
- Establish parameters to determine the dose.
- Determine the best conditions to carry out the process.
- Ascertain and clear obstructions or hindrances to get at the truth.
- Find the margin of errors, and eliminate their sources.

The narco-analysis, thus, follows the scientific processes. It is, therefore, a science. However, most of the persons (investigators, lawyers, judges and sensationalist media persons) who have to deal with Narco-analysis are not aware what science or its processes are. Some others, who are benefitted by its exclusion including crime syndicates, refuse to accept Narco-analysis as a science. It is unfortunate!

32.6 LEGAL MUDDLE

Narco-analysis interrogation is riddled with many legal controversies. The main legal issues, discussed in Indian courts, are:

1. Supreme Court Judgment[9] on Narco-analysis interrogation
2. Narco-analysis interrogation infringes/does not infringe Article 20(3) of the Constitution.
3. Narco-analysis interrogation tantamount to III Degree treatment of the subject
4. Narco-analysis interrogation is or is not in the ambit of Evidence Act.
5. Whose rights, of the criminal or of the public, are paramount?
6. Narco-analysis interrogation is an invasion of the privacy of the subject.

These issues have to be viewed dispassionately if Narco-analysis interrogation has to be accepted or rejected as a tool of investigation or a potent source of evidence in courts.

32.6.1 Supreme Court on Narco-analysis

In 2010, a Bench of Supreme Court of India headed by the then Chief Justice of India who wrote the judgment (251 pages!) in which they have commented upon Narco-analysis and on other new branches of Forensics.

The salient features of the judgment, *vis-à-vis* Narco-analysis interrogation are:

1. The Narco-analysis interrogation to be done only with the consent of the subject before a magistrate.
2. Nobody to be forced to undergo the test involuntarily.
3. The material and other evidence derived from the Narco-analysis interrogation can be used as evidence under section 27 of the Indian Evidence Act.
4. Direct evidence from the narco-analysis interrogation (confession!) is inadmissible unless supported by other evidence.
5. Involuntary interrogation amounts to III degree methods and the court cannot permit such tests.
6. The compelling public interest cannot justify ignoring right against self-incrimination.

9. *Mst. Selvi v State of Karnataka,* AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

7. Parliament may make law to make the test admissible in compelling public interest cases.

The only setback to the police is that involuntary **n**arco-analysis interrogation is not allowed. It is unfortunate that in serious crimes where it is needed most and where hardened criminals are involved who would not consent to take the test; the police is deprived of the scientific facility.

It is equally unfortunate that the state governments failed to put up facts before the court completely and lucidly to show that even involuntary narco-analysis interrogation is not unconstitutional for the following reasons:

1. Narco-analysis interrogation is carried out by a Forensic Psychologist. He just unravels the memory. The information so extracted may explicate (or implicate) the subject. The psychologist does not know its value, nor does he care for the same. He just records it through audio and video films. It becomes evidence only when the investigator evaluates it *vis-à-vis* the circumstances of the case.

   In the infamous Nithari serial murders, narco-analysis interrogation indicated that Pandher did not take part in the murdering process!

2. The blood from a suspect is drawn with a syringe needle day in and day out for identifying murderers, rapists and other sex criminals, for determining disputed paternity, and for other serious or petty crimes. No court has ever declared such blood drawl as unconstitutional. Rather they have ordered drawl of blood in many a case. (In Tewari's Disputed Paternity case when he refused to give blood court ordered to take the blood forcibly). In Narco-analysis interrogation, the anaesthetist uses a syringe only to inject a hypnotic which is also used in therapy.

   We cannot have two standards for the dissemination of justice. If the use of needle is constitutional in one type of cases, it has to be so in other type of cases also.

3. It is unfortunate that it was not brought to the notice of the court that during narco-analysis interrogation, the drug does not cause any pain to the subject. Rather the subject is relieved of any pain or worry from which the subject might have been suffering. By no stretch of imagination one can equate Narco-analysis interrogation with III Degree methods. It is unfortunate the prosecution failed to explain/convince the court.

4. The Supreme Court in an earlier judgment[10] has clarified that:

   Article 20(3) "**does not say that an accused person cannot be compelled to be a witness".** It says that such a person **"cannot be compelled to be witness against himself".**

   The question therefore is whether the accused is "furnishing evidence" against himself. If we consider the extraction of evidence from memory layers by scientific methods then where is the question of the subject furnishing the evidence? He is not furnishing any evidence. It is being taken into possession like other evidence (fingerprints or footprints from an unwilling accused). As taking of fingerprints or footprints does not attract infringement of article, 20(3) Narco-analysis interrogation also does not infringe the article of the Constitution.

It is unfortunate that the scientific facts and parity of the evidence with other evidence were not brought to the notice of the court to prevent injustice to narco-analysis interrogation.

32.6.2 Narco-analysis and Article 20(3) of Constitution

Article 20(3) of the Indian Constitution has the statement:

No person accused of an offence can be compelled to be a witness against himself

10. *State of Bombay v Kathi Kalu Oghad,* AIR 1961 SC 1808 : (1962) 3 SCR 10 : (1961) 2 Cr LJ 856 (SC).

The relevant contents of the above have two elements: firstly

no person accused of an offence can be compelled

and secondly,

to be a witness against himself.

It is true that most of the persons put to narco-analysis interrogation are accused of some offence(s). However, they are neither compelled nor are they witness against themselves.

No one is compelled to give evidence against himself. In fact the consent of the subject is taken before he is subjected to Narco-analysis interrogation. In a recent case[11] the Gujarat Laboratory refused to carry out Narco-analysis interrogation because the accused refused to give consent for the test. Thus, there is no compulsion to undergo the test. Further, the accused persons are often ready to undergo the test to get them explicated of the accusation.

In Nithari serial murders there were two accused; Surrender Koli and Mohinder Singh Pandher. Both girls. (CH)

The subject undergoing narco-analysis interrogation is not a witness against himself. In fact, information is being extracted from him like other evidence: blood for DNA analysis, fingerprints and footprints for comparison, etc. The law has allowed extracting the latter types of evidence even forcibly, against his will.

Further, the information is not evidence until it is evaluated and compared with the circumstances of the cases. The evaluation may even exonerate the subject as has happened to Mohinder Singh Panther in the notorious Nithari serial killing case.

In narco-analysis interrogation, the accused does not become a witness against himself. He does not give the information. The information is extracted from his memory by scientific methods by scientists following standard procedures. The evidence obtained is just like the evidence extracted from the accused in murder, rape or other cases in which the culprit leaves blood, flesh, skin, saliva, etc. at the crime scene or with the victim. Information of the source is obtained only when blood is extracted from the accused, analysed and matched with the corresponding data from the incriminating evidence. Both the enacted and case law has allowed the practice. In some cases, even courts have ordered extraction of blood.[12]

Extraction of evidence through narco-analysis interrogation by qualified scientists under proper condition has to be treated at par with the blood extraction of blood evidence if we want to avoid the charge of ignorance, bigotry and judicial chauvinism.

The utility and acceptance, by the courts, of the evidence has to depend upon the quality of evidence, its proper processing and presentation.

In short, narco-analysis interrogation does not infringe the sub-article 20(3) of the Indian Constitution.

32.6.3 Narco-analysis: New *Avatar* of III Degree Methods

Narco-analysis interrogation is no new *Avatar* of III Degree methods. In fact, as already seen, it gives relief from pain and worry and thus acts as a calming balm to the subject. Those who call Narco-analysis interrogation as a new type of III degree mode are perhaps unaware that the drug used in Narco-analysis interrogation is a barbiturate which is a therapy drug normally given to calm down agitated (stressed) persons. It does not inflict any pain; instead, it eliminates pain and worry. Consequently, it is blasphemy to equate it with III degree methods.

11. *State FSL Gandhinagar; Rao* case.
12. In *N.D. Tewari's* case on refusal to give blood, Delhi High Court ordered him to furnish blood.

32.6.4 Rights of Public Paramount

One can understand that no innocent person should be convicted but does our Constitution or lawmakers intend that the criminal be let loose on public on flimsy grounds? Whose interest the government, the legislature and the judiciary watch and protect, of the teaming millions or of a handful of criminals? There can be no two opinions or answers to this question. The interest of the public takes precedent.

Science has made tremendous progress in recent times. The criminal is using science to the hilt to carry out his nefarious activities. The law keepers are hindered from using modern science: flimsy law points, corruption, avoidable administrative delay, low priority to modernise scientific investigations, etc. Consequence: the criminal gets away with the crime; which emboldens not only him but also others with criminal tendencies. Most of the criminals in heinous crime are acquitted, because:

1. Wrong notions of law and justice
2. Topsy-turvy priorities of the government and of various wings of criminal justice system
    - The government does not create adequate scientific facilities including scientific manpower
    - The police dance attendance upon VIPs instead making the criminal do the dancing.
3. Prosecutors give free hand to the defence lawyers (and courts) for many reasons.
4. The judges are bound to old order. Some years ago a trial judge remarked, "Let me explode the myth of scientific evidence once forever," Others go on prolonging cases for years, again, for many flimsy reasons.

The sorry state of affairs continues.

The public interest is paramount. If the privacy of the culprit, who has shattered the home life of the victim, suffers; nothing is lost. Likewise, if the culprit has to suffer some inconvenience, no harm is done. The subject has to bear such burdens if the public interest, at large, has to be paramount.

32.7 CONCLUSION

Narco-analysis interrogation is a scientific technique. It is not another Avatar of III Degree Methods. The drug (a barbiturate) used is hypnotic. It involves no mental and physical torture of the subject. Rather it relieves the subject from pain and worries while its effect lasts. The interrogation lasts only for minutes at a time.

Narco-analysis has proved its utility in many a case. It is no invasion into the privacy of the subject as the examiner asks questions relating to the offence(s) in hand and there is no wild goose chase.

Narco-analysis has some oddities, which are being tackled by the scientists and are being removed with the passage of time.

32.9 CASE LAW

32.9.1 Supreme Court on Narco-analysis in 21st Century[13]

1. The legal questions in this batch of criminal appeals relate to the involuntary administration of certain scientific techniques, namely narco-analysis, polygraph examination and the Brain Electrical Activation Profile (BEAP) test for improving investigation efforts in criminal cases.

This issue has received considerable attention since it involves tensions between the desirability of efficient investigation and the preservation of individual liberties. Ordinarily the judicial task is that of evaluating the rival contentions in order to arrive at a sound conclusion. However, the present case is not an ordinary dispute between private parties. It raises pertinent questions about the meaning and scope of fundamental rights, which are available to all citizens. Therefore, we must examine the implications of permitting the use of the impugned techniques in a variety of settings.

2. Objections have been raised in respect of instances where individuals who are the accused, suspects or witnesses in an investigation have been subjected to these tests without their consent. Such measures have been defended by citing the importance of extracting information which could help the investigating agencies to prevent criminal activities in the future as well as in circumstances where it is difficult to gather evidence through ordinary means. In some of the impugned judgments, reliance has been placed on certain provisions of the Code of Criminal Procedure, 1973 and the Indian Evidence Act, 1872 to refer back to the responsibilities placed on citizens to fully co-operate with investigation agencies. It has also been urged that administering these techniques does not cause any bodily harm and that the extracted information will be used only for strengthening investigation efforts and will not be admitted as evidence during the trial stage. The assertion is that improvements in fact-finding during the investigation stage will consequently help to increase the rate of prosecution as well as the rate of acquittal. Yet another line of reasoning is that these scientific techniques are a softer alternative to the regrettable and allegedly widespread use of 'third degree methods' by investigators.

3. The involuntary administration of the impugned techniques prompts questions about the protective scope of the **'right against self-incrimination',** which finds place in Article 20(3) of our Constitution. In one of the impugned judgments, it has been held that the information extracted through methods such as 'polygraph examination' and the 'Brain Electrical Activation Profile (BEAP) test' cannot be equated with 'testimonial compulsion' because the test subject is not required to give verbal answers, thereby falling outside the protective scope of Article 20(3). It was further ruled that the verbal revelations made during a Narco-analysis test do not attract the bar of article 20(3) since the inculpatory or exculpatory nature of these revelations is not known at the time of conducting the test. To address these questions among others, it is necessary to inquire into the historical origins and rationale behind the 'right against self-incrimination'. The principal questions are whether this right extends to the investigation stage and whether the test results are of a 'testimonial' character, thereby attracting the protection of article 20(3). Furthermore, we must examine whether relying on the test results or materials discovered with the help of the same creates a reasonable likelihood of incrimination for the test subject.

4. We must also deal with arguments invoking the guarantee of '**substantive due process'** which is part and parcel of the idea of 'personal liberty' protected by article 21 of the Constitution. The first question in this regard is whether the provisions in the Code of Criminal Procedure, 1973 that provide for 'medical examination' during the course of an

13. *Mst. Selvi v State of Karnataka,* AIR 2010 SC 1974 : 2010 AIR SCW 3011 : (2010) 7 SCC 263.

investigation can be read expansively to include the impugned techniques, even though the latter is not explicitly enumerated. To answer this question, it will be necessary to discuss the principles governing the interpretation of statutes in light of scientific advancements. Questions have also been raised with respect to the professional ethics of medical personnel involved in the administration of these techniques. Furthermore, article 21 has been judicially expanded to include a 'right against cruel, inhuman or degrading treatment', which requires us to determine whether the involuntary administration of the impugned techniques violates this right whose scope corresponds with evolving international human rights norms. We must also consider contentions that have invoked the test subject's 'right to privacy', both in a physical and mental sense.

5. The scientific validity of the impugned techniques has been questioned and it is argued that their results are not entirely reliable. For instance, the Narco-analysis technique involves the intravenous administration of sodium pentothal, a drug, which lowers inhibitions on part of the subject and induces the person to talk freely. However, empirical studies suggest that the drug-induced revelations need not necessarily be true. Polygraph examination and the BEAP test are methods, which serve the respective purposes of lie-detection and gauging the subject's familiarity with information related to the crime. These techniques are essentially confirmatory in nature, wherein inferences are drawn from the physiological responses of the subject. However, the reliability of these methods has been repeatedly questioned in empirical studies. In the context of criminal cases, the reliability of scientific evidence bears a causal link with several dimensions of the right to a fair trial such as the requisite standard of proving guilt beyond reasonable doubt and the right of the accused to present a defence. We must be mindful of the fact that these requirements have long been recognised as components of 'personal liberty' under Article 21 of the Constitution. Hence, it will be instructive to gather some insights about the admissibility of scientific evidence.

32.9.2 Narco-analysis Technique

41. This test involves the intravenous administration of a drug that causes the subject to enter into a hypnotic trance and become less inhibited. The drug-induced hypnotic stage is useful for investigators since it makes the subject more likely to divulge information. The drug used for this test is sodium pentothal, higher quantities of which are routinely used for inducing general anaesthesia in surgical procedures. This drug is also used in the field of psychiatry since the revelations can enable the diagnosis of mental disorders. However, we have to decide on the permissibility of resorting to this technique during a criminal investigation, despite its' established uses in the medical field. The use of 'truth-serums' and hypnosis is not a recent development. Earlier versions of the Narco-analysis technique utilised substances such as scopolamine and sodium amytal. The following extracts from an article trace the evolution of this technique, [Cited from: C.W. Muehlberger, 'Interrogation under Drug-influence: The so-called Truth serum technique', 42(4) The Journal of Criminal Law, Criminology and Police Science 513-528 (Nov-Dec. 1951) at pp 513-514]:

> *With the advent of anaesthesia about a century ago, it was observed that during the induction period and particularly during the recovery interval, patients were prone to make extremely naive remarks about personal matters, which, in their normal state, would never have revealed.*

Probably the earliest direct attempt to utilize this phenomenon in criminal interrogation stemmed from observations of a mild type of anaesthesia commonly used in obstetrical practice during the period of about 1903-1915 and known as 'Twilight sleep'. This anaesthesia was obtained by hypodermic injection of solutions of morphine and scopolamine (also called 'hyoscine') followed by intermittent chloroform inhalations if needed. The pain relieving qualities of morphine are well known. Scopolamine appears to have the added property of blocking out memories of recent events. By the combination of these drugs in suitable dosage,

morphine dulled labour pains without materially interfering with the muscular contractions of labour, while scopolamine wiped out subsequent memories of the delivery room ordeal. The technique was widely used in Europe but soon fell into disrepute among obstetricians of this country, largely due to over dosage.

During the period of extensive use of 'twilight sleep' it was a common experience that women who were under the drug influence, were extremely candid and uninhibited in their statements. They often made remarks, which obviously would never have been uttered when in their normal state. Dr. Robert E. House, an observant physician practising in Ferris, Texas, believed that a drug combination which was so effective in the removal of ordinary restraints and which produced such utter candor, might be of value in obtaining factual information from persons who were thought to be lying.

Dr. House's first paper presented in 1922 suggested drug administration quite similar to the standard 'twilight sleep' procedure: an initial dose of < grain of morphine sulphate together with 1/100 grain of scopolamine hydrobromide, followed at 20-30 minute intervals with smaller (1/200 - 1/400 grain) doses of scopolamine and periods of light chloroform anaesthesia. Subjects were questioned as they recovered from the light chloroform anaesthesia and gave answers which subsequently proved to be true. Altogether, Dr. House reported about half-a-dozen cases, several of which were instrumental in securing the release of convicts from State prisons, he also observed that, after returning to their normal state, these subjects had little or no recollection of what had transpired during the period of interrogation. They could not remember what questions had been asked, nor by whom; neither could they recall any answers which they had made."

42. **The use of the 'Scopolamine' technique led to the coining of the expression 'truth serum'**. With the passage of time, injections of sodium amytal came to be used for inducing subjects to talk freely, primarily in the field of psychiatry. The author cited above has further observed, Id. at p. 522:

> *During World War II, this general technique of delving into a subject's inner consciousness through the instrumentality of narcotic drugs was widely used in the treatment of war neuroses (sometimes called `Battle shock' or 'shell shock'). Fighting men who had been through terrifically disturbing experiences often times developed symptoms of amnesia, mental withdrawal, negativity, paralyses, or many other mental, nervous, and physical derangements. In most instances, these patients refused to talk about the experiences which gave rise to the difficulty, and psychiatrists were at a loss to discover the crux of the problem. To intelligently counteract such a force, it was first necessary to identify it. Thus, the use of sedative drugs, first to analyze the source of disturbance (narco-analysis) and later to obtain the proper frame of mind in which the patient could and would 'talk out' his difficulties, and, as they say 'get them off his chest' – and thus relieve himself (narco-synthesis or narco-therapy) - was employed with signal success. In the Narco-analysis of war neuroses a very light narcosis is most desirable. With small doses of injectable barbiturates (sodium amytal or sodium pentothal) or with light inhalations of nitrous oxide or somnoform, the subject pours out his pent-up emotions without much prodding by the interrogator.*

43. It has been shown that the Central Investigation Agency (C.I.A.) in the U.S.A. had conducted research on the use of sodium pentothal for aiding interrogations in intelligence and counter-terrorism operations, as early as the 1950's [See 'Project MKULTRA – The CIA's program of research in behavioural modification', On file with Schaffer Library of Drug Policy, Text available from <www.druglibrary.org>]. In recent years, the debate over the use of 'truth-serums' has been revived with demands for their use on persons suspected of involvement in terrorist activities. Coming to the test procedure, when the drug (sodium pentothal) is administered intravenously, the subject ordinarily descends into anaesthesia in four stages, namely:

(i) Awake stage

(ii) Hypnotic stage

(iii) Sedative stage

(iv) Anaesthetic stage

44. A relatively lighter dose of sodium pentothal is injected to induce the 'hypnotic stage' and the questioning is conducted during the same. The hypnotic stage is maintained for the required period by controlling the rate of administration of the drug. As per the materials submitted before us, the behaviour exhibited by the subject during this stage has certain specific characteristics, namely:—

It facilitates the handling of negative emotional responses (*i.e.*, guilt, avoidance, aggression, frustration, non-responsiveness etc.) in a positive manner.

It helps in rapid exploration and identification of underlying conflicts in the subject's mind and unresolved feelings about past events.

It induces the subject to divulge information, which would usually not be revealed in conscious awareness and it is difficult for the person to lie at this stage. The reversal from this stage occurs immediately when the administration of the drug is discontinued.[14]

45. The personnel involved in conducting a 'narco-analysis' interview include:

1. a forensic psychologist,
2. an anaesthesiologist,
3. a psychiatrist,
4. a general physician or other medical staff and
5. a language interpreter if needed. Additionally,
6. a videographer is required to create video-recordings of the test for subsequent scrutiny.

In India, this technique has been administered either inside forensic science laboratories or in the operation theatres of recognised hospitals. While a psychiatrist and general physician perform the preliminary function of gauging whether the subject is mentally and physically fit to undergo the test, the anaesthesiologist supervises the intravenous administration of the drug. It is the forensic psychologist who actually conducts the questioning. Since the tests are meant to aid investigation efforts, the forensic psychologist needs to closely co-operate with the investigators in order to frame appropriate questions.

46. This technique can serve several ends. The revelations could help investigators to uncover vital evidence or to corroborate pre-existing testimonies and prosecution theories. Narco-analysis tests have also been used to detect 'malingering' (faking of amnesia). The premise is that during the 'hypnotic stage' the subject is unable to willfully suppress the memories associated with the relevant facts. Thus, it has been urged that drug-induced revelations can help to narrow down investigation efforts, thereby saving public resources. There is of course a very real possibility that information extracted through such interviews can lead to the uncovering of independent evidence which may be relevant. Hence, we must consider the implications of such derivative use of the drug-induced revelations, even if such revelations are not admissible as evidence. We must also account for the uses of this technique by persons other than investigators and prosecutors. Narco-analysis tests could be requested by defendants who want to prove their innocence. Demands for this test could also be made for purposes

14. "Laboratory Procedure Manual — Forensic Narco-Analysis," Directorate of Forensic Science, Ministry of Home Affairs, Government of India, New Delhi, 2005; Also see John M. Macdonald, "Truth Serum", 46(2) The Journal of Criminal Law, Criminology and Police Science, July-August 1955, pp 259-263.

such as gauging the credibility of testimony, to refresh the memory of witnesses or to ascertain the mental capacity of persons to stand trial.

Such uses can have a direct impact on the efficiency of investigations as well as the fairness of criminal trials. [*See* generally: George H. Dession, Lawrence Z. Freedman, Richard C. Donnelly and Frederick G. Redlich, 'Drug-Induced Revelation and Criminal Investigation', 62 Yale Law Journal 315-347 (February 1953)]

47. It is also important to be aware of the limitations of the 'narco-analysis' technique. It does not have an absolute success rate and there is always the possibility that the subject will not reveal any relevant information. Some studies have shown that most of the drug-induced revelations are not related to the relevant facts and they are more likely to be in the nature of inconsequential information about the subjects' personal lives. It takes great skill on part of the interrogators to extract and identify information which could eventually prove to be useful. While some persons are able to retain their ability to deceive even in the hypnotic state, others can become extremely suggestible to questioning. This is especially worrying, since investigators who are under pressure to deliver results could frame questions in a manner that prompts incriminatory responses. Subjects could also concoct fanciful stories in the course of the 'hypnotic stage'. Since the responses of different individuals are bound to vary, there is no uniform criteria for evaluating the efficacy of the 'narco-analysis' technique.

CHAPTER 33

CRIMINAL PROFILING IN FORENSICS[1]

SYNOPSIS

33.1 General 1579
33.2 Nature 1580

33.12 Additional Readings 1598

33.1 GENERAL

Profiling

"Most efficacious in cases where an unknown perpetrator has displayed indications of psycho-pathology"

Holmes and Homes, 1994

Urbanisation in India is spreading like a wild fire. It has created many law and order problems. Among the important ones are the anonymity and the hiding facilities the cities are offering to the criminal. A criminal can commit a crime and roam about in the city with impunity. The case of Raghav Raman of Mumbai is a revelation!

Raman Raghav was a serial killer who operated in the suburbs of Mumbai in the sixties of the last century. He killed at least 35 persons with an iron rod, bent at right angle and sharpened

1. The discussions in this chapter mainly centre on serial murderers and sex murderers of all types.

at the shorter end. He would give just one blow at the temple. There was hardly any person who survived after his attack.

*His victims were poor people from slum area and pavement sleepers. He would attack them around 1 AM. He did not know any of them. Revenge, sex or money was not his motives. He killed them because '**God ordered him**' to do so as per his statement. He was a true psychopath serial killer.*

The police did get a profile of the criminal but it was of limited use. (CH)

In such cases, however, profiling of an unknown criminal provides significant help. An experienced profiler can draw a reasonably good profile that can help in the identification/apprehension of the culprit, the psychopathic killer or other criminals.

They provide many idiosyncrasies in the execution of their nefarious task, which constitutes thumbprints of their *modus operandi*, which lead the law enforcement agencies to them. A profile does not identify the culprit. It only describes his personality traits, which reduced the field of search and investigation. Definite identification is based on physical evidence like DNA, fingerprints, or other clue clues, which the culprit exchanges with the victim, the scene (and articles thereon), the weapon of offence or transport used.

Profiles of the criminals provide multi-purpose help to indicate the criminals:

- Assess the motive of the criminal,
- Indicate particular types of physical evidence at the scene, which help to link the criminal to the crime, and
- Suggest interrogation mode.

Criminal profiling is useful in a variety of cases where an unknown criminal is involved and who is not easily traceable, including the following types:

1. Sex murders including sadistic murders where the body is mutilated.
2. Serial killings.
3. Racist killings.
4. God-ordained or **"visionary"** killings.
5. "Missionary" killings.
6. Ritualistic murders.
7. Schizophrenic killings; here the culprit "pre-empts" the assaults of an imaginary foe.
8. Organ theft cases.
9. Corpse mutilation cases.
10. Cannibalism cases.
11. Some arson cases.
12. Paedophilic cases.

33.2 NATURE

Criminal profiling is also known as psychological profiling, offender profiling, behavioural profiling, criminal personality profiling or criminological profiling. FBI has named it as a Criminal Investigative Analysis (CIA).

Criminal profiling is an investigative tool used by the investigating agencies to identify likely suspects and to analyse patterns to predict the offender's future offences and victims (predictive profiling).

Criminal profiling process uses the action and behaviour of the criminal (or in their omission) at the crime scene; to profile his mental, emotional, physical and other personality characteristics in the commission of the crime. The FBI has created a Behaviour Assessment Unit. It helps to analyse the collected data to guide investigations by interpreting the offender's behaviour during the crime and the interactions between the offender and the victim during the commission of the crime as displayed in the crime scene.

Criminal profiling means to create a word picture (with or without a sketch) of an unknown criminal whose antecedents are not known nor are they easily available. This developed criminal profile helps the investigators to reduce the area of search and the number of possible suspects for locating the unknown criminal and to indicate his identifying personality features. The profile does not claim to pinpoint the identity of the criminal though it may indicate the socio-geographic background, health status, mental aberrations and his lifestyle.

Current applications of criminal profiling in criminal cases mainly include predictive profiling, sexual assault offender profiling, and case linkage.

Criminal profiling is based upon his behaviour, actions and utterances in a given situation, his actions at the crime scene(s) his treatment of the victim, his language/dialect and his utterances, including use of slangs and expletives at the time of the incident. Criminal Profiling also takes into consideration his choice of the scene, handling of the scene, the *modus operandi* he has adopted, his arrival and departure (time, mode and route) from the scene, his disposal of the victim or the available evidence, which reflect upon his personality: behaviour, thoughts and actions. The profiler may also predict his future activities and guesses the past misdeeds he had done.

Profiling is also used in civil situations. The mode and motives may be different. They were and are used in varied tasks including some of the following nature:

1. Military Selection Boards in India have been employing specialists to profile the candidates appearing for the selection of officers' rank for decades to ascertain their suitability for military service.
2. Some Bank Staff Selection Boards have been procuring profiles of job seekers mainly from the honesty, devotion to duty and loyalty angles.
3. Business tycoons, entering into a partnership, get profiles of their would-be partners.
4. In the selection of spouse, some persons get profiles of the would-be life-partners before marriages.

The methods of profiling and the intensity of inputs in civil profiling vary tremendously. In fact, most of the profilers follow their own techniques. However, the FBI has put in tremendous effort and has come up with a profiling system which is being adopted by most of the specialists in the USA, with minor variations, if any.

Induction of profiling to locate criminals has boosted the use of profiling. Rather, criminal's profiling has taken the centre stage in the field. The TV has promoted its popularity. But it must not be forgotten that profiling is only a help to identify. Further, it is applicable only to a certain type of crimes where a psychopath is on the rampage. Serial killings and sex murders are its main targets; motiveless arson and visionary and missionary murders also fall in its ambit.

Criminal profiling involves large work force and considerable funding.

33.3 THE CRIMINAL

Who is a criminal whose profile is needed in a criminal investigation? Naturally, he is usually an unknown entity who has committed a serious crime. He may or may not be a recidivist.

Usually, he is a recidivist (repeats the same type of heinous crime time and again). He is involved in heinous crimes like murders, sexual offences including sex murders, ritual murders, sadistic and hedonistic (perverse pleasure) murders. In hedonistic murders, the killer is mentally perverse. He enjoys pain, shock and death in others. Some of them enjoy blazing fires and indulge in arson.

The criminal profiling subjects are usually mentally abnormal. They may be schizophrenic, sex maniac (hyper-sexed person), psychotic, psychopathic and pyromaniacs. The mental abnormality may be inborn, acquired or social maltreatment may have thrust it upon him. A drug addict or an alcoholic may acquire the abnormality through abuse of drugs or drunkenness. An excessively maltreated person in childhood or adolescence may lose mental balance and may like to settle scores with the society as a whole. He loses a sense of human feeling or decency. He takes pleasure in vindictive anti-social acts and goes on committing them until he is controlled (arrested and imprisoned). The general name given to such mental imbalance is Psycho-Pathetic Disorders.

What is the motive of a psychopath to commit the crime? The traditional crime movers: Zun, Zamin and Zar [Female (sex), property and money] are there and will remain there; but they do not account for all the criminals under the scan. Some psychopaths are "ordained" by the almighty; or, so they believe! There are **"visionary**" who see visions that spur them to kill certain persons. They kill. Random killers and Sect killers fall in the category. Prostitute killers are self-appointed scavengers to clean the area from the prostitute, whore harbinger of sex spread diseases and other social evils. Racists, like Nazis, are "missionaries" oriented to make the world free from some community. Impulse stirs other criminals to abnormal behaviour. Emotional tyranny may end in anger, fear, compassion, depression and cause abnormal behaviour. The ego of the culprit may need self-certification of power and sex drive. Revenge for real or imaginary ills against individuals or a class of individuals may again be a dominant motive.

Hedonist (thrill seekers) and sex maniac form perhaps the majority of the culprit subjects for criminal profiling on whom serious profilers work to create their profiles.

The factors, which promote criminality, are inborn biology, disturbed family life, criminal environment, lack of proper education and abject financial and social constraints in life. *Jhungi Jhaunpari* (Ghettos) dwellers often fall prey to become such criminals.

33.3.1 Criminal's General Portrait

The criminals who commit heinous crimes and are recidivist (repeaters) haves two main personality traits: the general traits and the crime-specific traits.

The general criminal traits of the criminal are:

1. He has no remorse or regrets for the heinous acts of crime, he commits.
2. He does not stick to any profession.
3. He is slip-shod in his actions.
4. He has no respect for the law, social norms or social behaviour. He breaks them **repeatedly** with impunity, for his gains or to satisfy his unholy desire for lust or sadistic pleasure. He is law unto himself.
5. He is a liar, a cheat and a con artist.
6. He is selfish.
7. He is impulsive. Takes the decision at the spur of the moment without prior consideration or planning.

8. He is easily irritated and picks up fights with one and all, without any regard to his or opponents safety.

There are two types of criminals under the scan: those who carry out their nefarious trade meticulously (organised); those who carry out their criminal activity haphazardly. They are disorganized criminals. The two types leave different types of evidential trails in their commission of crime.

33.4 PROFILER

33.4.1 The Profiler

Profiler is a person who creates criminal personality profile of a criminal from his action, utterances, writings, behaviour towards the victim, his *modus operandi*, his action at the scene, choice of the site and the time. The created profile can provide answers to many questions, including the following questions about the crime and the criminal, with varying degrees of certainty:

1. Who is the criminal?
2. Which is his residential area?
3. What is his dialect?
4. What are his body characteristics (body built)?
5. What are his psychopathic traits?
6. Is he an organised or disorganized person?
7. What is his social status?
8. What is his educational standard?
9. What was his motive to commit the crime?
10. What is the Hallmark (distinguishing feature) of his criminal acts?
11. What type of victim does he choose?
12. What type of site does he choose for the crime?
13. At what time does he strike?
14. When and where will the criminal strike again?
15. What is his IQ?

33.4.2 Qualifications

The profiler is a new entity. He ties the loose ends of the different types of data, applying logic, psychology, knowledge, crime data relating to the case in hand and of similar other crimes. He thus creates a physical, mental, and emotional profile of the likely criminal.

The main qualifications of the profiler are:

1. A master's degree in criminal psychology; preferably a Ph. D. degree.[2]
2. Training in profiling.
3. Attachment with a seasoned profiler for a considerable time.

These qualifications are indispensable. In addition, the profiler should have a highly developed sense of rationalisation, a deep understanding of the crimes, criminals and criminology.

2. Gives him confidence (Research methodology!) and laces him with better respectability.

The profiler creates profiles independently, only after he has acquired considerable experience of working with a seasoned profiler. Then and then only, he will be able to meet the challenges of correct profiling of the criminal.

Basic education in psychology or criminology is a good starting point. Augmentation of the skill through training is a must. Attachment experience is indispensable. However, to be a top bloke in the profession, the person must have a keen interest and a deep sense of honesty, dedications to the science and devotion to the work and profession. He must be a man of science. He goes only by the dictates of data, observes the laid down norms, shuns hunches, intuition or dictates of superiors. He knows the negative power of Conformation Syndrome and avoids it. He does not hesitate to consult a fellow specialist(s) in refractory cases. Above all, he keeps up with the Joneses in the profession.

33.4.3 State of the Art

The need for correct criminal profiling is immense in modern society where anonymity is the rule, and it is increasing. But there are few profilers in India. The number must go up. It is hoped that the situation will improve in the coming times.

33.5 CRIMINAL PROFILING PROCESS

33.5.1 Criminal's Profile

Criminal profiling is both an art and science. It involves the contribution of a number of professionals for collecting the basic data on which the profile is based. An ideal profile of a criminal consists of many elements including the following:

1. Age, sex, and body built of the criminal,
2. Educational standards of the subject,
3. Language or dialect from his utterance; dialect may indicate the area of origin,
4. Possible vocation, if any
5. Addiction, if any
6. Behaviour including mannerism in handling the victim,
7. Social background,
8. *Modus operandi*,
9. Choice of victims,
10. Enticement mode,
11. Transport used,
12. Choice of site(s) for the criminal act, modes of ingress and egress,
13. Manner of disposal of the victim,
14. Efforts to keep the act secret, and
15. Periodicity of such occurrences.

It is rare that a profiler gets all the data to give information on all the above elements of the profile. However, he tries to get data on as many of the elements as he can and provides a workable profile.

33.5.2 Aims of Profiling

Profiling has, in brief, intends to:

1. Fix identity of an unknown criminal through profiling.
2. Assess the type of victim-culprit syndrome and prevent recurrence of similar crime by the same criminal.
3. Recognise the field of operation of the subject; and guard the area and apprehend the criminal red-handed when he strikes again.
4. Provide *"portrait parle"* (sex, age, race, marital status, and employment status) of the criminal to help his arrest and to pre-empt occurrence of similar incidence.
5. Provide guidelines about the nature of scene of crime and the expected evidence thereon.
6. Indicate the likely social group and residential area of the criminal.
7. Create a psychological portrait of the subject.
8. Furnish guidelines for interrogation.
9. Give additional information on any of the elements of Profile.

The scope of criminal profiles is expanding. It is possible that profiling may be used to know the unknown criminal in less heinous crime also; once the stage for profiling is set at a reasonable expense of time and money.

33.6 DATA FOR PROFILING

> **"It is a capital mistake to theorise before one has the data"**
>
> **Sherlock Holmes**

Profiling is a complex task of collecting relevant data, evaluating and fixing it in the jigsaw puzzle to frame a profile. The data collection is the basic task. If it is insufficient, incorrect or wrong, the efforts of the profiler will be futile; the created profile will mislead. Data collection needs a lot of time and effort and hence it is costly and time-consuming.

A worthwhile profile of a criminal needs a lot of information. A profiler alone cannot and does not gather all the needed information. The assistance and joint efforts of many persons create the needed synergic effect.

The following main sources provide the needed data:

1. The victim;
2. The crime scene;
3. The utterances of the culprit;
4. The culprit's treatment of the victim before/after death;
5. The medico-legal or post-mortem report;
6. The written communication of the culprit, if any; and
7. The pattern of criminal's actions—*modus operandi*.

33.6.1 Victim

The victim is an important source of evidence. Live victims provide information and data about the criminal. The profiler gets the details from the live victims through interrogations and interviews. He can understand the culprit (and the victim) better and can get clarifications he may need at times about the details of the occurrence, the *modus operandi* and the part played by the victim in resisting the onslaught; from which an accurate profile is built.

The victim may be incoherent due to shock or fear. The profiler may have to use special techniques (hypnosis) to extract the correct and complete details.

However, in most of the cases, the victim is dead.

The dead also furnishes important and substantial data if a competent and experienced medico-legal expert examines the dead. All should join hands to get the maximum information.

The evidence obtained from the victim about the culprit is:

1. Antecedent evidence Physical description,
2. Physical action,
3. Culprit's utterance,
4. Drunk or under the influence of drug(s),
5. Post crime action,
6. Transport used.

33.6.1.1 Antecedent Evidence

It is possible only if the victim is alive and knows the culprit. It is almost non-existent. The knowledge helps the profiler.

The antecedent evidence about the victim is usually known. It is obtained from his or her family, friends, acquaintances, neighbours, office colleagues and co-workers. The persons who had business dealings or household staff are also useful sources to know about the personality of the victim. The information plays an important part in profiling the offender. It can answer the main question of the profiler:

"Why was this victim selected by the culprit?"

In addition, the knowledge of the antecedents of the victim helps the profiler to develop a clear picture of victim's:

- Physical health
- Working schedule
- Physical features
- Emotional personality
- Psychological personality
- Promiscuous?
- Addicted?
- Alcoholic?
- Living style, habits, including office or household routine?
- Risk involved for both the victim and the culprit. Risk factors often determine not only the crime scene site but also the *modus operandi* of the crime and the extent and pattern of injuries. They may also necessitate advance planning.

The profiler takes these aspects in building the profile of the offender along with the *modus operandi*, the planning and the skill of the culprit in the execution of his task.

33.6.1.2 Evidence on Victim

The evidence on the person of the victim and apparel thereon help to build up the profile of the offender.

The evidentiary clues blood, semen, saliva, skin, flesh, hair, bite marks, (DNA!), fibres, bullets, their marks, injuries and wounds provide the clinching linkage and identity of the culprit in many a case where the offender is apprehended.

A medico-legal expert provides the evidence available on the person of the victim. He answers to the many questions[3]:

The clothes on the victim also provide evidence for profiling and identification of the culprit. Provocative apparel, tears and stains on them and the extent of exposure of the corpse are significant to indicate the events which took place at the time of assault; or, before or after the assault.

33.6.1.3 Oral Evidence

If the victim survives the attack of the culprit, she or he will be the most important information source about meeting, luring, mode of transport, the language he used the places to which he took and the all the violent or non-violent acts he performed against the victim. The wealth of information facilitates the work of the profiler to build up a profile of the criminal. The profiler must interview the victim at the earliest to get all the useful details.

The victim can also narrate the utterances of the culprit which are useful to the profiler to indicate the area from which the culprit hails, educational standard and societal standing.

Live victims are sometimes so frightened or shocked that they are unable to assist the investigations through direct interviews. Other methods of interrogations have to be tried. Hypnosis has proved effective in some cases.

33.6.1.4 Offender's action profile

The action profile of the culprit *vis-a-vis* the victim is the primary source of information, which not only helps to peep into the mind of the culprit but also provide linkage between similar crimes *via* the injury patterns.

The semen, blood, skin and flesh on the person of the victim may provide clues which provide definite identification of the culprit.

The following evidence needs careful consideration:

- The utterances (language, accent, slangs, per words abuses) of the culprit
- The culprit's treatment of the victim before/after death
- Written communication of the culprit, if any
- The pattern of criminal's actions—his *modus operandi*.

3. *Supra.*

33.6.1.5 The Medico-legal Expert

The Medico-legal Expert is an important source of information in profiling the culprit. In addition to indicating the nature and cause of death, the weapon used and the number of injuries, their fatal or non-fatal nature and their sites. he provides answers to questions:

- Why so many injuries? Were they needed to kill?
- Pattern (sequence) of injuries?
- Cause: sadistic pleasure?
- Victim's resistance?
- Mental imbalance?
- Infuriated?
- Cannibalistic action?
- Body part taken as souvenir?
- Necrophilia act performed?
- Knowledge of Anatomy?
- Surgical (or butcher's) skill?
- Serial killer; recidivist [similar case(s) examined before]?
- Correspondence with other case(s) examined before?
- Body naked? How were the clothes taken off?
- Clothes torn? Pattern?

33.7 THE INVESTIGATOR

The investigator is the main actor in the process of gathering evidence for criminal profiling. He does all the legwork, so much needed in the process of the collection of evidence. His main activities in the process include the following:

1. **Handles the multi-site scenes:** records them video graphically, photographically, by sketching and by textual description; notes oddities at the scene and collects physical clues including, prints, impressions, odours and objects.
2. **Interrogates (Interviews) the victim:** (if alive); witnesses and suspect(s) at the earliest so that the interviewee does not forget the details, does not rationalise, does not add hearsay evidence or gets biased for one or more of the numerous reasons.
3. **Gets the victim examined:** from an experienced medico-legal expert.
4. **Utilises the services of/profiler/forensic psychologist/forensic psychiatrist**: in India, it is a big problem. We have hardly any seasoned profilers, forensic psychologists or Forensic psychiatrists though you might get quite a few charlatans. In the USA, on the other hand, some police department has them on their roll or they have them on-call basis (contract basis!).
5. **Collects and puts all the evidence before the profiler**:

   It includes:

   - all documentation of the scene (including video film, photographs, sketches and description script),

- **statements of the witnesses** and the victim and the findings of the background information of victim,
- details of other similar cases whether they are geographically relevant or irrelevant, and
- his own assessment about certain person(s) with reasons for linking them with the crime.

6. **Provides any additional help:** or information the profiler may require.

The major tasks of the investigating officer are:

- Gathering circumstantial Evidence
- Examination of Scene of occurrence
- Crime Scene
- Collection of intelligence

33.7.1 Circumstantial Evidence

The investigator has to do a lot of legwork to find out the evidence surrounding the incident. He tries to:

- Establish the site of the main occurrence and its geographical feature if it is an outdoor site and whether it is frequented or a deserted place?
- Ascertain if the contact/enticement/assault was pre-planned.
- Fix the timeframe: contact time with the victim/enticing time/assault time.
- Identify the possible culprit as relative/intimate mate[4]/acquaintance/colleague/stranger.
- Guess/ascertain the motive.
- Compare the incident pattern with other similar occurrences.

33.7.2 Crime Scene[5]

Crime scene possesses a wealth of information which goes a long way to a create a criminals profile. Usually, the crimes under the scan are multi-scene crimes. They involve occurrence site(s), hiding site, disposal site and carriage vehicle**.** These are the places where the culprit and the victim meet each other also come in contact with the crime scenes and the objects thereon. The contacts exchange traces mutually.[6] These exchanged trances and the disturbances and disorders provide a wealth of information useful for criminal profiling. However, the crime scene must be processed professionally and without delay.

Police investigator handles the scene but in important cases, the following professionals assist them:

1. Forensic Expert
2. Medico-legal Expert
3. Imaging Expert

The tasks these experts perform are well-known and need not be repeated. The chief police investigator remains the chief of the team.

For the systematic handling of the scene, the investigating officer has to:

4. Living-in couples are coming up in Indian cities.
5. For detailed handling of the crime scene, see Chapter 5 "Scene of Occurrence".
6. Locard's Law of Exchange!

1. Barricade the scene.
2. Put a guard on the scene to prevent unauthorised entry to the scene.
3. Walk through the scene to assess the need of the scene and requisition the needed help.
4. Record (with the assistance of imaging expert) the scene through:
   - Video film
   - Digital photography
   - Sketches
   - Textual description

   Proper documentation of crime scene is mandatory. Videography preserves the scene indefinitely. Thus, check and recheck are possible. The scene can be taken to the courts even after years!
5. Locate and fixes the positions of evidentiary clue photographically and through sketches.
6. Collect packs and dispatches the evidence to the concerned quarters with appropriate queries.

   In all the processes he ensures that the identity (*vis-à-vis* the case), integrity (no contamination no mutilation, no obliteration, no destruction), and continuity of the chain of possession (through possession log) is maintained.
7. Prepare a crime scene report.

The evidence at the scene is varied. It may be odour(s) or scents, prints and impressions, marks, objects [evidentiary clues including corpse(s)] or even the disturbance and disorder pattern. All are properly recorded, collected and got evaluated. They all help in criminal profiling. For example:

1. The size of the foot/footwear marks indicate the height and built of the culprit.
2. Tyre marks indicate the type of vehicle used. The tyre marks may also indicate the routes taken by the culprit to reach and leave the crime scene. The vehicle, indirectly, indicates the lifestyle of the culprit.
3. The blood spatters may indicate a fight or attempt at getting away.
4. The broken and or overturned furniture may indicate self-defence.
5. Blood, saliva and semen, through DNA, link or de-link a suspect with the crime.
6. Left-over object like purse, keys, and handkerchiefs can indicate the personality/identity of the culprit.
7. Hair left at the scene may indicate the ancestry and the identity of the culprit through DNA.
8. Traces like the smell of putrefaction of flesh, blood, body parts even maggot may indicate the hiding place of the body and the duration for which it has been kept.
9. Traces of narcotic drugs or their packing material may indicate that the culprit (or the victim) is/was drug abuser/addict.

The importance of proper evaluation of the crime scene can never be over-emphasised.

33.7.3 Collection of Intelligence

The local police also develop intelligence system in their own area. The police head gets information periodically (daily in some jurisdictions) about new visitors, incidents and of trouble spots. If the culprit is a newcomer, the local informer may be in a position to give a working portrait of the individual.

Information about the criminal, the victim and about the situational environment is highly beneficial in building the criminal profile. The collection of the intelligence thereof is an important aspect of the investigation of blind murders or rape-murders. Sources of information other than the police informers are:

1. Neighbours
2. Panwaries (who sell pan and cigarettes)
3. Chowkidars (guards)
4. Chance witnesses

The information from these sources can guide the investigation about the possible culprit, about the character and lifestyle of the victim and her or his contribution towards the crime thereof, motive and sometimes the time element and mode of the occurrence.

33.8 CASE HISTORIES

Sex murders and serial murders were not very frequent in India. However, they are increasing with speed. During the first decade of the 21st century, the rape cases increased by fifty %!

33.8.1 Nirbhaya case[7]

> *The latest case in Delhi is an example of extreme brutality! An educated woman was waiting for a bus at one of the bus stands along with her educated friend. A private bus came and offered a lift. Both the persons boarded the bus as they were getting late.*
>
> *It was about 9.30 pm. The bus had curtains drawn on the windows. There were 6 persons (friends?) in the bus drinking and making merry. Soon after they caught hold of the persons beat the man and raped the girl. She resisted the rape. So she was brutally attacked and injured. After satisfying their lust, they threw the two on the road side. They were picked up by a passerby and taken to a hospital. The man survived the injuries but the girl in spite of the best medical aid succumbed to them after fighting the odds for about a week.*
>
> *The doctors who attended upon the girl, remarked that they have never seen such a brutal attack in sexual assault.[8] (CH)*

The investigators and especially the profilers must study these cases in-depth whether they have been successfully investigated or are still pending apprehension of the culprit. The study is highly rewarding. In rare cases, it may link the case in hand with another case(s). That, of course, will be a great find. But otherwise also the case studies are highly useful to understand the criminal mind, the varied motives and, more importantly, the varied *modus operandi* used to commit the heinous crimes under the scan.

Data of similar cases from far and wide in time (decades) and space (whole country) should be collected.

---

7. There were six criminals of the brutal murder-rape case. One committed suicide during the trial, one was juvenile and sentenced per the prevailing law. The remaining four were sentenced to death by the trial court, confirmed by the high court. The Supreme Court maintained the death sentence.[2017 *Mukesh v State for NCT of Delhi,* Criminal Appeal Nos. 607–08 of 2017, SC, Decided on 5 May 2017. Bench: Dipak Misra, R. Banumathi, Ashok Bhushan].
8. Five persons were prosecuted. The sessions court sentenced four of them to death and the fifth who was a juvenile, was sent to juvenile home in September 2013.

33.8.2 TV Serials and Films

In every country, there are TV serials or films on serial murders and sex crimes. Their CDs should form part of the profiler's library. In fact, these serials and films often excite the evil mind. They might have adopted (or may adopt in future) the ideas and the modes exhibited therein to commit such heinous crimes.

33.9 PROFILING PROCESS

33.9.1 Assumptions

The profiling process, under discussion, relates mainly to serial murders, sex and sadistic murders, visionary and missionary murders. The process presumes the following assumptions:

1. The culprit is male. The process, however, is also applicable to the female criminal.
2. The profiler is a well-qualified and experienced professional.[9]
3. The profiler is provided with all the relevant, correct and reliable data from the crime scene by a seasoned, experienced and dedicated investigator (or a dedicated investigating team!) for such work. The data include complete documentation (video film(s), photographs, sketches, script description, statement of witnesses and investigator's report). He is informed about the idiosyncrasies of the crime scene, if, any, while submitting the data.
4. A senior medico-legal expert, preferably with a team, collects the evidence from the person of the victim including the clothes. He gives all the important details: the number of injuries, their sequence, fatal or non-fatal injuries, superfluous injuries and sadistic injuries. He documents any extraneous material(s) found on the victim and recovered. The types of weapon used the force with which the injuries were inflicted. are also described. The expert should be available to the profiler for conference so that he can get odds and ends cleared from the medico-legal expert if he so needs.
5. The intelligence about the strangers and vagabonds in the area is trustworthy, collected by reliable and experienced sources.
6. The culprit reflects his personality in the various acts of omissions and commissions in enticing the victim, his activities at the crime scene or while he was with the victim before and after the crime.
7. Behaviour of the offender is consistent in the series of crimes he commits. Thus, use of linkage analysis is valid to inter-link similar cases and link them to one offender because of the similarities that are present.

33.9.2 Process

Profiling is a multipoint process:

Firstly, the profiler acquires the data about the crime, the crime scene, *modus operandi,* behaviour towards the victim, idiosyncrasies, disposal mode of the body or bodies and his post-action behaviour. Or, he has to contend with the data which the investigator(s) and others have been able to scrabble to build up the possible (perfunctory, partial or complete) profile.

Secondly, the profiler assesses the crime and the criminal:

1) Isolated case

9. *Supra*, p 1394.

2) Serial murder
3) Sex murder/crime
4) Sadistic murder
5) Ritual, missionary or visionary murder
6) Murderer's typology. Psychopath or mentally deficient. Organised or disorganised. Educated, semi-literate or illiterate?
7) Drug addict?
8) Alcoholic?

Evidence is searched for motive and risks for the culprit and the victim, personality traits and the time element of the various steps involved in the crime and time interval and the areas in the serial crimes.

Thirdly, the profiler fixes the jigsaw puzzle of the profile by taking over mentally the role of the victim as well as that of the culprit and evaluates the possible actions and reactions of the culprit and the victim for the emergence of the evidence found at the scene and on the victim. He especially notes what the abnormal features are in the act of crime and what the offender's individualistic idiosyncrasies are, which may form the crime thumbprint of the criminal *vis-à-vis* the crimes. If all the important pieces of evidence do not fit in the profile structure, the structure is abandoned and another profile structure is envisaged and tried. The process goes on ununtil the profiler believes that he has hit the right structure in which the incidents of the crime fit in.

The experience of the profiler in other cases and that study of other profiler's reports/ investigations go a long way for correct assessment/prediction about the culprit.

What are the contents of an ideal criminal profile?

The profiler uses both inductive and deductive logic to extract culprit's features, working habits, lifestyle, geographical location, vocation, and behaviour from the evidence and come up with a profile which explains the various events of the crime.

The modes of evaluations and deductions of the profilers vary from one specialist to another. All the processes are highly complex and beyond the scope of the present discussions. However, every profiler usually concentrates on the following aspects:

1. Stature: height, built, the footprints, the gait pattern and other clues help in estimating the stature.
2. Age, sex, ancestry.
3. Appearance.
4. Relationship with the victim.
5. Educational standard.
6. Language (including vocabulary and slangs) used at the scene or in the note(s) sent to police or others.
7. Vocation, if any.
8. Addiction, if any.
9. Behaviour including mannerism in handling the victim.
10. Social background.
11. Area of origin, residential area(s) and places frequented.

12. *Modus operandi.*
13. Choice of victims.
14. Enticement mode.
15. Transport used.
16. Choice of the site(s) for the criminal act, modes of ingress and egress, disposal of the body.
17. Manner of disposal of the victim.
18. Efforts to keep the act secret.
19. Indications of cannibalism if any.
20. Taking body parts as souvenirs.
21. Periodicity of the occurrences.

The volume of information and its correctness in the profile largely depends upon the culprit's actions: how unique they are, how much evidence he left and to what extent the left over evidence is amenable to interpretation for profiling. Culprits in all cases cannot be profiled. The profiles also vary in their contribution towards identity indication. A few may be at the target, the other may be half-truths and still others may not only miss the bus but may mislead the investigations. Criminal profiling therefore is yet to receive proper respectability. But it is an important assistance to the investigator and is gaining more and more reliability and hence importance. The scientists, therefore, have to improve their tools and techniques so that it becomes a more useful weapon in the armoury of the crime investigators.

33.9.3 Profiling Modes

Every profiler has his own methodology for profiling, as seen earlier. But the profiling process has also to vary according to the nature of the crime and the available evidence at the scene, with the victim and other sources.

In general, three modes: FBI mode, Canter Mode, and Turvey mode are being used in criminal profiling.

33.9.3.1 FBI Mode[10]

FBI has made the criminal profiling (also called criminal analysis) into a six step process:

1. **Profiling Inputs:** In this step the total available information from all sources is collected and submitted to the profiler. He evaluates the evidence and compares the same with the evidence available in similar cases.
2. **Decision Process Models:** In this step the profiler tries various hypothetical models and tries to co-relate the evidence with each model.
3. **Crime Assessment:** The crime in hand is then assessed *vis-à-vis* the model presented by the profiler to assess whether the details of the crime fit with the likely behaviour of the criminal.
4. **Criminal Profile:** Finally the given profile is accepted (or rejected, and a new profile is prepared). The details of the model are then furnished to the investigators, giving some reasons on some details.

10. F.B.I. Mode (VI-CAP- CSA).

5. **Investigation:** The profile is then circulated among all concerned including public in some cases. The persons with similar profiles are located, profiles compared and those persons with whom it comes closest are investigated covertly or overtly.
6. **Apprehension:** Once the match is found and some evidence against the person is secured, the suspect is apprehended: to extract clinching evidence to link or delink him with the crime case in hand.

33.9.3.2 Canter's Statistical Mode[11]

Canter' a candid approach is based upon statistical data compiled from the records of the criminals from various sources including court records, police records, prison records and hospital records. The data is classified according to various parameters to type the criminal. The following important parameters are included in typing the criminal and to build his profile:

1. Typology of the criminal
2. Type of the crime
3. Motive for the crime
4. Behaviour at the crime scene
5. General behaviour of the criminal
6. Time and place of commission of the crime
7. Treatment of the victim

Canter utilised a large amount of data to segregate the criminals into several groups and went on adding new data from new cases. He would, then match the data of the given unknown criminal and would create the profile of the unknown criminal.

33.9.3.3 Turvey's Behaviour Evidence Analysis[12]

Turvey was of the firm belief that, for profiling, scientific evidence must be utilised to get worthwhile results. His Behaviour Evidence Analysis technique involved three elements: Forensic evaluation of the evidentiary clues and their correct interpretation; the study (profiling) of the victim and thorough inspection of the scene and gathering all the evidence available thereon to collect data on the following points:

1. **Evidence evaluation:** The incident involves a lot of evidence exchanged by the participants. The total evidence (material clues, disturbance, scents, odours, photographs, video graphs, sketches, marks, patterns) all tell a story. They must be evaluated in proper crime related perspective.
2. **Disposal site:** The site of the disposal of the victim and other articles involved in the crime provides a lot of information in profiling.
3. **The witness:** The witnesses at or around the crime scene or passers-by may have observed, seen or heard things some of which may be helpful to create a viable criminal profile. They need careful consideration.
4. **Post-mortem examination:** The autopsy (or injury report in case the victim is not dead) speaks volumes of the mind of the killer and provide a lot of information for

11. Canter, D. 1995, *Criminal Shadows*; Harper Collins, London.
12. Turvey, BE, *Criminal Profiling*, Academic Press, London, 1999.

compiling the criminal's profile. The post-mortem examination must be done by a competent expert and in its entirety to get its full value for evaluation.

5. **Victimology:** The main addition to the usual aspect of profiling is Turvey's stress on careful study of the victim, his actions and behaviour to find out:
   - What was the background (age, health, sex, residence, profession, lifestyle, circle of friends (and enemies) and business partners) of the victim?
   - Why was the person chosen?
   - Where and how was the victim picked up, carried, killed and disposed off?
   - Was the victim known (or unknown) to the culprit?

A complete profile of the victim is highly useful. It should be as complete as that of the criminal. It is easier to build the same whether the victim is living or dead.

In addition to the above, there are other techniques of profiling being practised. In fact most of the profilers use their own modes, though they may be similar to any of the above three. In fact they are variations of the same most of the time.

33.9.4 Recent developments in processing

There are many new approaches towards profiling, including the following:

1. **The 3-pronged approach:** it utilises the criminal investigative approach, the clinical practitioner approach, and the scientific statistical approach singly or severally.
2. **The 5-steps approach**: it analyses the criminal act and compare it to similar crimes in the past, carries out in-depth analysis of the actual crime scene, assesses the victim's background and activities for possible motives and connections, considers other possible motives and finally develops a profile of the possible offender. The five assessments are:
   - obtaining data from all sources,
   - evaluating the data and identifying significant features of each crime in the series,
   - classifying the significant features as either modus operandi or ritualistic,
   - comparing the combination of modus operandi and ritual or fantasy-based features across the series to determine if a signature of the suspect exists,
   - The last step is to write a concise, precise and intelligible report.
3. **FBI BAU UNIT**: it uses a 6-stage process to develop a criminal profile: profiling inputs, decision process models, crime assessment, criminal profiling, investigation, and apprehension.

33.10 SOME PROFILES

33.10.1 Jack the Ripper

"Jack the Ripper" operated in the south east part of London in 1880s. He raped and killed at least a dozen women in that part of the city. He simultaneously challenged the police to catch him. The police tried but could not lay hands upon him. Ultimately, they utilised the profile created by Dr. Thomas Bond who was a police surgeon. His profile of Jack the killer indicated:

1. Only one person was responsible for at least five out of the seven murders in which he had carried out the post-mortems of the victims.

2. The killings were sex murders, involving sadistic behaviour.
3. The culprit was a strong, composed and daring loner
4. He was probably hypersexual.
5. The culprit had no anatomical knowledge. Hence, he could not be a doctor or a butcher.
6. His outwardly appearance: quiet, innocent look; middle-aged person; neatly attired wearing a cloak probably
7. No fixed occupation

A person was arrested on the basis of the profile and convicted. Some people cried foul that the accused was not the real Jack the Ripper[13]. (CH)

33.10.2 Adolf Hitler

Adolf Hitler, who was a dictator in Germany, was responsible for World War II. In 1943, the US Strategic Service Unit decided to get a behavioural and psychological profile of Hitler. Dr. WC Langer, a psychoanalyst, was commissioned to do the needful.

Dr. Langer studied the utterances and writings of the dictator and also interviewed people who knew the dictator and prepared the profile and gave it to the authorities. The findings in the profile have since been published[14] in the form of a book.

The main features of the profile are:

1. Hitler was meticulous about his dress and appearance.
2. He was healthy and unlikely to die natural death during the war.
3. In case of defeat, he would not seek asylum in a neutral country; he would probably commit suicide.
4. He had manic tendencies and he was deteriorating mentally.
5. He was prone to sadism.
6. He was a loner.
7. He was not a good conversationalist.

The profile generally corresponded with Hitler's character. The US government was interested in the final scenario; it took place as per prediction. Hitler did commit suicide on the eve of surrender. (CH)

33.10.3 Serial Bomber

George Meteskey was an infamous serial bomber of USA. He exploded bombs in public places in New York City during 1940-1956. When the police failed to trace the bomber they requisitioned the services of a profiler, Dr. JA Brussel, a psychiatrist, working in mental hygiene department of the city.

Dr. Brussel studied the crime scenes (from photographs) and the mail the bomber sent to press. He built up a profile of the bomber:

1. The bomber is a heavy built unmarried single middle-aged man who wears a double-breasted coat.

13. Relatively recently DNA profiling of seminal stains and bloodstains matched with a suspect's DNA. The suspect was Aaron Kosmink, a Jew Polish barber; a different person from the one convicted, more than 100 years ago, on the basis of criminal profiling.
14. WC Langer, *The Mind of Adolf Hitler,* 1972.

2. He is a Roman Catholic immigrant. He is a skilled mechanic. He lives in Connecticut.
3. He has a strong grudge against the Electric Power Supply Company (Consolidate Edison) and wants to takes revenge against it. (He exploded the first bomb in its Headquarters).

The above profile proved useful to the police. They guessed that the culprit has to be a past or present employee of the company. The check-up led them to Meteskey who, on arrest, confessed to the bombings. The prediction of the profiler was true to the very letter.

"Meteskey was an ex-employ of the company. He was a heavy built unmarried middle-aged single man who wore a double-breasted coat. He was a Roman Catholic immigrant skilled mechanic, living in Connecticut." (CH)

33.10.4 David Meirhofer

David Meirhofer was a sadist sex murderer. In June, 1973 he abducted a seven year girl in early hours of the morning in Rocky Mountains in USA, from a tent. He overpowered her and she could not wake her parents who were sleeping nearby. Intensive and extensive search proved futile. The case was referred to Teten and Mulley, of the FBI, for profiling the culprit.

Teten and Murray studied the available data and came with a profile:

1. The culprit was most likely a young white male.
2. He was a sex killer.
3. He mutilated the bodies of the victim after killing.
4. He takes away sometimes body parts of the victim as souvenirs.

The police investigation on the basis of the profile led to the arrest of David Meirhofer who was a 23 old single white male. Search of his residence revealed body parts not only from the girl but also of another female. (CH)

33.11 CONCLUSION

Criminal profiling, as an aid to reach the unknown criminal, is apparently a very attractive mode to fight crime. It is very popular with the public and the media. Scientifically it is a tough nut to crack in spite of the fact that it has given dramatic results in some cases. But the present-day technology does not meet the requirements of criminal profiling. Extensive research is needed to make criminal profiling viable.

An ideal profile contains physical description of the culprit, his education standard, his behaviour pattern, his vocation, his social standing, his background, the geographical region from which he hails, his motives, his abuse of narcotics and most importantly, his idiosyncrasies (body parts collection!) in his behaviour before, during and after the commission of the crime. What else is needed to apprehend him? Practically nothing! But so far all the above elements are not available and the reliability of those which are available in some cases, is not quite trustworthy, beyond a reasonable doubt. The profiling has, therefore, not achieved the acceptability level of other branches of Forensics. Predictions of profiles are often half-truths. Some even mislead. Researchers are trying to make it a more reliable tool in the fight against crime. However, all said and done, criminal profiling has certainly limited utility in the investigation of crime.

The dead tells his tale

34.1 GENERAL

34.1.1 Forensic Anthropology

Anthropology has been providing evidence to the courts for centuries now, without the qualifying word **"Forensic"**. It is a recent addition to distinguish it from general Physical Anthropology or from other branches of Anthropology. The work relating to the specialty has increased so much that it did need a separate name. Thus, the *Avatar* has its new name **"Forensic Anthropology"**.

The word "Forensic", now known so well, means "pertaining to court or law". Anthropology means the science that deals with mankind, his evolution, changes in him over the passage of time and his activities in all its varied forms. It has many branches dealing with various aspects like social, biological (including DNA[1]), medical, archaeological and physical anthropology. However, the main branch that is helping the dissemination of justice is physical anthropology.

Physical anthropology is concerned with the physical aspects of the human body, their characteristics, developments and changes which take place continuously not only in a lifetime but also even after death. The body characteristics, continuous development and changes in the body are the wherewithals, which provide the Forensic Anthropologist with the evidentiary clues to assist the courts in deciding anthropological problems in criminal and civil cases. It also helps to identify lost persons under various circumstances including those who lose their memories.

Forensic Anthropology is, thus, the application of the science of Physical anthropology in the dissemination of justice. It follows its basic tenets and uses its tools and techniques. It has also developed (and is developing) its own tools and techniques with vengeance.

Forensic Anthropology helps to solve legal problems in which humans, their dead bodies, skeletons, bones or their fragments are involved.

Bite marks identifications are included in Forensic Anthropology by some physical anthropologists. However, since the development of Forensic Odontology as a separate speciality, the bite marks are included in the newly developed branch, **"Forensic Odontology".**

34.1.2 Forensic Anthropologist

Forensic Anthropologist has to be one:

1. Who is educated in physical Anthropology, has been trained in Forensic Anthropology, is engaged in research in the same or related field(s), and has published papers to his credit, works as Forensic Anthropologist?
2. Who has been initiated to the speciality through attachment, for a considerable time, to a renowned and experienced Forensic Anthropologist, working in a respected University or Institute, where Forensic Anthropology work is done routinely?
3. Who has acquired ample practical experience in solving legal problems involving Forensic Anthropology during his attachment period(s), and later?
4. Who is interested in the field and takes up the professional challenges seriously?
5. Who does not start with a pre-conceived idea about the outcome of the case he takes up? He starts the examination with an open mind. Collects both positive and negative evidential data and goes by the preponderance of the data.
6. Who does not accept the dictates of his intuition, hunch or supernatural revelations?
7. Who remains a man of science? His inferences flow from the observations he made and the data he collected during the examination.
8. Who has no enemy to punish and no friends to be saved?
9. Who is immune to temptation, influence and bias?

10. Who is aware of the Conformational Syndrome,[1] considers it and avoids it scrupulously.
11. Who has a liaison with Forensic Pathologists, physical Anthropologist, Osteologist and fellow Forensic Anthropologists? He consults them in all refractory and borderline cases.

34.1.3 Evidentiary Clues

Evidentiary clues in Forensic Anthropology are human beings, alive or dead, children or infants, young or old, males or females; but only when they are involved or concerned with some legal issue(s). The dead may be in any form: unchanged, dismembered, disfigured, mutilated or putrefying at various stages of putrefaction, skeletal remains (complete or partial), bones (one or more) or their fragments. They are all evidentiary clues if they are involved in criminal or civil investigations and trials.

34.1.4 Possibilities

Given proper questioned and standard evidentiary materials, equipment and expertise, Forensic Anthropologist can provide important forensic assistance pertaining to anthropological clue materials from his identity to the identity of his ancestry.

34.2 PRACTICAL POLICE WORK (PPW)

The location, collection, preservation and dispatch of the evidence relating to abandoned, lost or hidden dead bodies in varied forms (complete, disfigured, dismembered, putrefied, skeletonised or only bones) to the Forensic Anthropologist is the task of the law enforcement agencies.

34.2.1 Fundamentals

1. The identity (*vis-à-vis* the crime), authenticity, integrity and continuity of the chain of possession of the evidence seized, collected, preserved and stored is maintained beyond a reasonable doubt, through proper documentation and, whenever possible, through eyewitnesses. Proper inventory on the label tag, properly secured (sealed!) packages and movement log of the evidence go a long way to maintain the identity and integrity of the evidentiary clues.
2. All actions (seizure, processing, movement and storage) taken *vis-à-vis* the evidentiary clue is properly recorded on the case file or the register as per departmental instructions, for later verifications and production in the court, if required.
3. Forensic Anthropology is comparatively new to India and so far it is not utilised frequently. An average investigating officer has neither the basic knowledge nor the training, nor any practical experience worth the name to handle or process Forensic Anthropology evidence. He needs help of a competent Forensic Anthropologist. The investigations, therefore, need **S**pecial **I**nvestigation **T**eam (**SIT**) to ensure proper investigations. SIT should consist of:
    - **Chief Investigator:** He is the team chief from law enforcement agencies (police!). He should be an experienced police officer. He will have the over-all responsibility to assemble the desired team (also additional manpower in cases like mass murders or disasters), collect the necessary tools, assign duties to the team members and oversee that the team, individually and collectively performs their duties efficiently and competently. He writes a report on the examination of the scene of occurrence after completing its examination.

1. It is unconscious desire, on the part of the expert, to prove what has been suggested to him by the referral authorities.

- **Documentation Officer:** He has to be a technician of high order to document the work done at the scene. Photographic and video coverage of the scene and the evidence thereon is his main task. Preparation of site plan [sketches of the scene] including evidence thereon and recording the scene and the evidence may be his additional duties.

  Sometimes the services of a draftsman are requisitioned to prepare the site plan, especially in expansive and important scenes like those in mass murders or disasters.

  Descriptive documentation is sometimes done by the chief investigator himself.
- **Forensic Anthropologist:** guide technical aspects of seizure and preservation of the anthropological evidence. He is indispensable. In mass murders and disasters more than one Forensic Anthropologist may be needed.
- **Forensic Pathologist:** In massive death scenes like mass murders, mass disasters or extensive wide ranging fires, Forensic Pathologist(s) and other doctors are also needed. Even when single body intact or putrefied, is the exhibit. It is the Forensic Pathologist(s) who takes up the examination first. Forensic Anthropologist starts his investigation after the post-mortem. He utilises the findings of the Forensic Pathologist(s) in his evaluations.

The U.S. Public Health System with the support of Government has organised a team of forensic specialists called DMORT (Disaster Mortuary Operational Response Team). It consists of forensic pathologists, radiologists, forensic anthropologists, forensic Odontologists, fingerprint experts, security officers, funeral directors, computer specialists, photographers, and others, all working to establish the identity of the victims and to investigate the circumstances surrounding their deaths. They respond to all declared mass fatalities.

Team members are on call 24 hours a day.

4. The scenes of crimes in skeletal remains offer only one chance for its examination in most of the cases. The handler of the incident scene has, therefore, to remember: **"Now or never"**.

34.2.2 Scene of Occurrence

The concept of the crime scene has changed completely in recent times. It is no longer the sole site where the incident took place. It is not the lone place where the *corpus delicti* is hidden. It is not the vehicle which carried the *corpus delicti.* It is not the house of the culprit or the victim. Generally, it is a conglomeration of those sites where evidentiary clues pertaining to the case are found. For Forensic Anthropological purpose, it is comparatively easy to specify incident scene. It is mainly the place where the dead or their remains are discovered or located. The sites vary:

1. **Mass Murders Site**: mass murders are killing incidents where numerous persons are done to deaths for varied reasons. The usual modes of mass murders are gasification (through poisonous or suffocating gases) explosions, arson, shooting or sabotage.

   There are numerous dead bodies at the mass murder sites. They include many mutilated unidentifiable bodies. Their identification is not only a social responsibility but it is also a legal requirement. The investigating officer has to do all the legwork and control, guide and supervise the work at the scene. The ultimate identification has to done by the Forensic Anthropologists and other specialists (Medico-legal experts, Forensic Odontologists and Forensic experts).

   In Twin Tower Trade Centre explosion (New York, 2001) about twenty per cent of the 973 mutilated bodies were identified through Forensic Odontology. (CH)

2. **Mass Disasters Site:** Aeroplane accidents, rail accidents, road accidents, landslides, earthquakes and other natural disasters (Tsunami!) occur every other day. The processing of these scenes is also one of the primary duties of police. There are often mutilated bodies at the scenes of occurrences. Forensic Odontology helps the police to identify them.

   In Tsunami disaster (2005) 90% of the mutilated bodies were identified through Forensic Odontology. (CH)

   The handling of the mass disaster scenes follows the pattern of handling mass murder scenes.

3. **Mass Graves:** When a large number of persons are killed or die together, they are often buried together, in big mass grave(s). Later the necessity to identify a person(s) from the skeletons in the grave might arise. The skeletons including dentitions are sometimes the only glues to the identity of the decedents.

   The body of the Adolf Hitler was buried along with about a dozen persons. It became essential to identify his body remains to make sure that he is dead as there were rumours that he has escaped and fled to South America and that the news of his suicide was inspired and fake. The bodies (in boxes) were exhumed and his body remains were identified through his unique dental record (available with his dentist). (CH)

4. **Miscellaneous sites:** The body and their remains may be found at other sites including the following:
   (a) Burial sites.
   (b) Graves in graveyards.
   (c) Secluded disposal sites in jungles, hills, mountains and ravines.
   (d) Wells and pits.
   (e) Ponds, canals, rivers, seas and oceans.
   (f) Homes (basements, walls, compounds), hotels and houses.

   Laila Khan, an actor, and her family had been missing since February, 2011. Police had not been able to make head or tail of the case until 10th July, 2012. On the day while searching the farmhouse of Laila, the police came across two water pits, in the compound of the house. The pits were covered with earth. Digging the two pits, the police unearthed six skeletons!

   The identity of the skeletons were confirmed through anthropological evidence (and later through confession of the culprits to be that of Laila and her family. (CH)

   (g) **Trains, buses and cars**: dead bodies are sometimes abandoned in the vehicles.

34.2.3 Action

The scene of occurrence is the place where the culprit, the victim, the tools of *modus operandi* and the site along with the paraphernalia thereon come into close contact *inter se.* They exchange traces, creating a plethora of connecting and identifying clues. The investigating officer is the master of the domain and collects the clues!

If the scene is handled properly, more than half the work is done. It is rightly said that the success or failure of the investigation of a case largely depends upon the handling of the scene.

In handling the scenes, where Forensic Anthropology is involved, the investigator follows the following protocol:

- **Surveys the scene**: he walks through the scene to assess the investigative requirement and see how best the scene can be handled.
- **Plans the examination** of the scene and handling of the evidence thereon

Proper planning is indispensable when the scene is of mass murders, mass disaster or an expansive graveyard. Such scenes need a large number of investigators, many and varied specialists, extensive equipment and paraphernalia for handling the injured, the dead, the mutilated and other evidence. It is really mind-boggling in some cases.

The needs of the scene and the time needed to process the scene vary according to the nature and dimensions of the incidence.

> *Robert Pickton (also known as Pig Pickton) was a serial killer He had killed scores of women, 49 according to his statement; mostly prostitutes from the nearby area of Vancouver, Canada. It was suspected that the killer had hidden the bodies in his pig farm (about 7 hectares in area). The search for the remains of the deceased was earnestly taken up in 2002. The salient features of the crime scene examination are:*
>
> 1. *The area was divided into segments of 20 x 20 metres, for exploration. Each segment was excavated to the sterile point (the depth at which the soil was not soiled by human or animal activity), which varied from one metre to about twelve metres.*
> 2. *The earth dug out was examined by Forensic Anthropologists – In addition to human remains they also eliminated 45000 bones as being of animals! It took 5 years to complete the examination of the scene of crime.*
> 3. *One hundred Forensic Anthropologists were employed to sift the excavated debris from which the human remains were to be identified. They could identify the remains of six women positively and gave probable identity of about twenty females more. DNA test was used for confirmation in all cases of identification of exhibits.*
> 4. *It was a massive clue hunt at a crime scene: In brief the handling of the scene involved:*
>
> | | | |
> |---|---|---|
> | (a) | Time taken: | >5 years |
> | (b) | Anthropologist employed: | >100 |
> | (c) | Exhibits collected and examined: | >600,000 |
> | (d) | Photographs taken: | ~ 400,000 |
>
> 5. *Pickton was given life imprisonment for the murders of the six identified women, in 2007.*
> 6. *It was the largest crime scene ever examined in Canada2. (CH)*

Search for the evidence (clues) is the most important task at the scene. The search is so arranged that no demarked area is left uncovered or unprobed.

The following search modes are employed in important and expansive scenes of incidents:

1. **Visual Search:** one or more investigators do the visual search. The scene is searched[3] thoroughly adopting strip, zonal, criss-cross or spiral method depending upon the scene and the number of the searchers available. Disturbed foliage, if the scene is fresh, is a good indicator of some activity at the site. Likewise, if the body or its parts are freshly buried the surface of the grave is comparatively soft. The investigator probes the earth and detects the softness of the grave area.
2. **Search Dogs:** specially trained dogs (also called cadaver dogs) to search dead bodies or their remains have been extensively used for a long time now. They locate hidden bodies or their parts or their remnants which are possibly scattered in a vast area.

   Properly trained dogs have proved better searchers than humans. They perform best when the scene is least disturbed or trampled over.

2. For details see: *lculbert@png.canwest.com*
3. Chapter 4 for details.

3. **Modern Trends:** modern scientific methods are proving extremely useful in handling some scenes.
    - **Aerial Photography:** it is now being utilised in expansive (air disaster) and important scenes. It registers the limits of the scene, shows inter-space relationship of different articles at the scene and indicates the disposition of the evidence *inter se*.

Fig. 34.2

Aerial Photograph of the Pickton's Pig Farm (part). It took 100 Anthropologist to literally unearth (using excavators) 600,000 exhibits from 7 hectare farm and to link some of them to a score of bodies of the missing female victims (supra).

- **Metal Detectors:** humans often carry metal objects like watches and mobiles. The murderer more often than not leave the item with the victim while disposing off the body. The metal detectors can detect such object and thus, indicate the possible presence of the victim's body or its remains.
- **Remote Sensing:** ground penetrating Radars are used to detect buried objects.
- **Excavators:** Specially modified excavators are used for removing earth in expansive scenes. They are used to excavate human remains from large areas. They remove soil or dirt up to depth of few centimetres at a time at a regulated pace. The Forensic Anthropological technicians scrutinize the excavated soil for any foreign material in the soil. It is collected.

DNA profiling of the bones and other body materials is possible in most of the situations. It offers foolproof identity of the remains. It is, therefore, used to confirm the anthropological identifications. The confirmation pre-empts the defence plea of non-identity successfully.

34.3 FORENSIC ANTHROPOLOGIST IN ACTION

Identification of bones, their fragment, skeletal remains (complete or partial) or mutilated or putrefied bodies, complete or dismembered, is mainly the task of Forensic Anthropologist. They also determine the age of living persons.

Formerly, the anthropologist used to work in the laboratories only. Now he also goes to the scene so that the evidence or full value of clues remain intact during location, collection, packing, dispatching or in transporting. If the investigating team has a Forensic Anthropologist on its role, the scientist must visit the scene. However, in mass disasters (Earthquakes, Tsunamis, hurricanes, typhoons, cloudbursts, massive fires) and mass murders, not one but many more Forensic Anthropologist are required.

The Forensic Anthropologist, in Forensic Anthropological investigations, helps to:

1. collect correct clues at the crime scene,
2. identify the clues in the laboratory, and
3. understand expert evidence, through written report/oral presentation.

In the USA, usually Forensic Anthropologist starts expert work only after certification from the Forensic Anthropology Board.

34.3.1 Forensic Anthropologist at the Scene

The presence of a Forensic Anthropologist at the crime scene likely to bear anthropological evidence is desirable to oversee the discovery, location and of collection of the evidence. In cases like those of mass graves, more Anthropologists are needed.[4] He helps the investigation in many ways:

1. **He helps to locate the clandestine grave(s):** disturbed foliage, virgin soil, variations in the surface soil structure (soft grave area, depression or mound formation and artefacts around indicate the clandestine grave(s).
2. **He helps in the excavation of evidence:** to prevent loss, contamination or missing of important evidence.
3. **He regulates the pace of digging:** to ensure complete recovery.
4. **He provides leads:** to locate the questioned/standard evidence.

The Forensic Anthropologist provides guidelines only. The investigator does the physical collections/Preservation/packing/sealing of the evidence; as per law in India.

34.3.2 Laboratory Investigations

Forensic anthropological laboratory investigations are varied, time consuming and often the results are inconclusive. The investigations are, therefore taken up only in when DNA profiling fingerprints or Forensic Odontology does not identify the exhibits. The main tasks of a Forensic Anthropologist[5] are to:

1. Identify human bone and their fragments.
2. Ascertain whether the bones are from one or more than one source persons.
3. Determine the time of death.
4. Ascertain the cause of death.
5. Ascertain the nature of death: violent or otherwise.
6. Find the ancestry of the deceased.
7. Locate deformity/bone Injuries, malformation or healed fracture(s,).
8. Reconstruct face.
9. Fix the identity of a given skull through superimposition.
10. Segregate co-mingled bones if they are from more than one individuals.
11. Ascertain his or her sex, age, stature, and height.

4. In *Pickton's* case (*supra*) 100 Anthropologists were employed.
5. The discussion in the present works is only elementary; the technical details have been omitted.

Brief descriptions of some of the important tasks are given below:

34.3.2.1 Human bones

The first and the important step in all bone identification problem is to ascertain whether they are human or animal bones.

> *In Pickton's case (supra) while searching for the remains of scores of women, the Forensic Anthropologists separated 65,000 animal bones or their fragments. They were mixed with the bones of perhaps 49 or more women. (CH)*

The human bone or its fragment are identified in the following ways:

- **DNA profiling;** is the best tests to establish the human origin of a bone.
- **Blood test;** Precipitin test anti-human serum indicates if the bone is of human origin or not. The bone must carry the blood proteins.
- **Bone structures;** of human beings are different from those of animals. Thus, the skull, denture or pelvis of human are easy to identify. However, in some cases bone piece may defy identification.
- **Composition of ash;** of human bones is different from that of animals.
- **Large bones;** vertebrae, shoulder blades and long bones help.

Bones of One or More Persons: determination, if the given bundle of bones is from one or more persons, is comparatively easy. The Forensic Anthropologist sorts out the identified human bones in two sets: bones from the left side on one side and from the right side on the other side. A similar site is fixed for bones from a second person, and so on. The number of bone sites, thus formed, gives the number of persons.

The expertise in Physical anthropology and osteology is indispensable for the work.

34.3.2.2 Age Determination

Age determination of the foetus, of the living, of the dead and of the skeletal remains is often required. The main methods or indicators are:

34.3.2.2.1 Eruption of Teeth

The eruption of teeth is a fair indicator of the age of a child or of an adolescent. The eruption time can vary from person to person. The following tables give an approximate idea of the age, based on the eruption of teeth:

Table 34.1

Eruption Schedule of Milk Teeth

S. No.	Tooth	Age of appearance (in months)	
		Lower jaw	Upper jaw
1.	Central Incisor	6	7-8
2.	Side Incisor	7	9
3.	I Molar	12	14
4.	Canine	16	18
5.	II Molar	20	24

The milk teeth are pushed out and their place is taken by permanent teeth in due course.

The eruption periods of the permanent teeth in the adolescent (and youth) are given in the following table:

Table 34.2

Eruption Schedule of Permanent Teeth

S. No.	Tooth	Age of appearance (in years)	
		Lower jaw	Upper jaw
1.	Central Incisor	6-7	7-8
2.	Internal incisor	7-8	8-9
3.	Canine	9-10	11-12
4.	I Premolar	10-12	10-11
5.	II Premolar	11-12	10-12
6.	I Molar	6-7	6-7
7.	II molar	11-13	12-13
8.	III molar	17-21	17-21

Number of teeth also indicates age. The table below is the rough guide:

Table 34.3

Rough guide of age from number of teeth

S. No.	Total teeth	Age (in years)
1.	20	3–5
2.	24 (addition of 4 first molars)	6–11
3.	28 (addition of 4 second molars)	12–17
4.	32 addition of 4 third molars	18-24 onward

34.3.2.2.2 Teeth Development

Teeth development has been utilised extensively to determine the age of adults from twenty-one years of age onwards. There are numerous factors in the development of teeth morphology that help to estimate the age of persons, live, dead or their skeletal remains. They are highly complex. Proper inputs, however, can provide a close estimate of the age. The main indicators are:

1) Completion of the denture.
2) Completion stage of roots (erupted teeth!).
3) Rate of formation of enamel
4) Attrition of the crown
5) Formation of cementum
6) Transparency of root dentine
7) Root surface re-sorption.
8) Discolouration and staining of teeth
9) Changes in the chemical composition of teeth

Forensic Odontologists are doing a lot of research in this field. It is hoped that the age estimates will be more accurate in the coming times.

34.3.2.2.3 Sutures' Closure

There are three types of sutures on the outer surface of the skull. They are open at the time of birth, but with time, they start closing. The extent of closures offers a guide to the age of the victim.

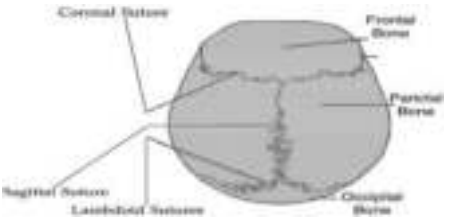

Fig. 34.3

Sutures on the Skull

34.3.2.2.4 Inner (endocrinal) Sutures

Forensic Anthropologists have studied the closures of endocrinal sutures of the skull. They found that they give a better estimate of age.

34.3.2.2.5 Epiphyseal Union

Epiphyseal union of various joints in the body gives fair estimates of the age of a victim. As in all physical growths, there are individual variations, absolute age cannot be given. The following table can be taken as a rough guide for the age.

Table 34.4

Age in years, from Completion of Acto-Epiphyseal unions

S. No.	Age	Body part
1.	14	Elbow
2.	15	Hands and feet
3.	16	Ankle
4.	17	Thigh
5.	18	Knee
6.	19	Wrist
7.	20	Shoulder
8.	21	Hip
9.	29	Clavicle (Proximal end)

34.3.3 Sex Determination[6]

The determination of sex of skeletal remains obviously was based upon the variations in the bone structures of male and females, which crop in due to different nature of work over the generations and lifestyles. It is an important step for the identification of the victim as it eliminates 50% of the victim suspects and it is almost the first step after the bones had been identified as human bones. However, sex determination from the bones is not an easy task. Even the experienced Forensic Anthropologist meets his Waterloo in this specialty. The reasons for the same are simple. The bony variations do not depend upon the sex alone; other factors intervene. Among the numerous factors the prominent ones are:

1. Race (ethnicity, ancestry),
2. Traditional division of labour (work) among the sexes through ages,
3. Working class or non-working class, and
4. Idiosyncrasies in bone structures.

In spite of the inhibiting factors, opinions on the sex of the remains were being given day-in and day-out, though the courts would take them with a pinch of salt. The Forensic Anthropologists take the following features into consideration while evaluating bones for sex determination:

34.3.3.1 General Appearances

The preliminary examination for sex differentiation relates to the general aspects of some bones. The table below is the one used for the purpose:

Table 34.5

Sex Differentiation

S. No.	Feature	Female	Male
1.	General size	Small	Large
2.	Architecture	Smooth	Rugged
3.	Supraorbital margin	Sharp	Round
4.	Mastoid Process	Small	Large
5.	Occipital bone	Muscle lines un-marked	Marked Muscle lines Protuberance
6.	Glabellas	Flat	Bony
7.	Gonial angle	Wide angle	Square
8.	Palate	Small parabola type	Large, u-shaped
9.	Occipital Condoyle	Small	Large

When the whole skeleton is available, and its ethnicity is also known, Forensic anthropologist using total evidence from all relevant parts, make fairly accurate identifications about the sex of the skeleton. However, the most important body parts are pelvis and skull in that order.

6. DNA, for sex determination has made the discussion on the subject redundant. Cortical and cranial **bones**, as well as teeth, were found to provide sufficiently preserved **DNA** for analysis. The **sex** was **determined** from skeletal remains of 18 individuals, including young children, out of 22 examined from periods ranging from 200 to around 8,000 years.

34.3.3.2 Pelvis

Pelvis carries many prominent reliable sex indicating formations. Nature has created female pelvis to allow the easy expulsion of the child at the time of delivery. The main difference used by the Forensic Anthropologists is the ischium and pubic index, which is the ratio of the lengths of the pubic and ischium. An easily identifiable distinguishing feature is the size of the hips. The male has narrow hips and the female has broad hips. A Forensic Anthropologist, in addition, carries out many other measurements to arrive at the correct conclusion.

34.3.3.3 Skull

Male and female skulls (cranium) also offer many points of dissimilarities. They help to distinguish the sex of the skeleton of the victim. For example, Forensic Anthropologists:

- Check the presence of ridges above the eye-sockets. They are present only in males.
- Scrutinise the bones below the ears and the occipital bones. They are sturdier in males than in females.
- Evaluate the skulls. They are smoother and smaller in females of the same ethnic group than those in males.

34.3.3.4 Examine jaws

Females have parabolic shaped and males have "U" shaped jaws.

34.3.3.5 Miscellaneous

If the Forensic Anthropologist is not satisfied with the data from the above evaluations, he examines other body parts:

- Bones: humerus, ulna, and femur
- Clavicle
- Scapula
- Tibia

They help. However, as noted above, the modes are no longer tried. DNA provides the way to determine sex from bone.

34.3.4 Mode of Death

When the whole body is available, a medico-legal expert ascertains the cause of death: natural, homicide, suicide, accidental or unknown. Forensic Anthropologist determines the cause of death from skeletal remains. It is possible only when the bones have been damaged he may be able to ascertain fall injuries, mechanical violence injuries, sharp edged weapon injuries or firearm injuries. Usually, he consults a medico-legal and Forensic expert for this determination.

34.3.4.1 Gunshot Injuries

Gunshot wounds are created in shooting cases. The firearms used vary. Shotguns, rifles, pistols and revolvers (either factory-made or improvised) are used. The projectiles may pass through bones, get embedded, graze along the bone. In almost all cases it is possible to identify the gunshot damage through:

- Characteristic entry wound formation, with crater formation on the exit point.
- Presence of projectile(s) or their fragments on the surface embedded in the body.

- Scraped material from the projectile around the projectile mark, including GSR (Gun Shot Residues)
- Embedded gunshot residue on the bone in close range shots where the bone is close to the skin (skull!).

Once skeletal remains were discovered in a jungle. It was sent to the local medico-legal expert. It was found that there were a number of pellet in the skeleton ribs. It was suspected that the victim had been done to death through shotgun shooting using pellet charge.

But who was the victim?

Police investigations revealed that some years earlier, a patient from a close by mental hospital had run away after he tried suicide with a shotgun. However, he had been X-rayed before he ran away. The pellet pattern on skeleton corresponded with the pattern on X-ray. (CH)

34.3.4.2 Blunt Weapon Damage

The blunt weapon may be a stone, a wooden stick, an iron bar or a pipe. The striking edge is blunt (as against sharp edge) and somewhat broad. Sometimes its blow is so forceful that it fractures the bone.

Blunt weapon injuries can be identified in most of the cases and in some cases; the nature of the weapon can also be identified.

34.3.4.3 Cut Marks

Sharp-edged weapon cause cuts to create incised wounds. Knives, swords, Kukris, sickles and axes. create the cut marks. They may be through and through cut or hole or partial cuts. The sharp-edged weapons can also cause stab wounds.

A hand magnifier improves the visual examination. Radiography helps to locate invisible embedded materials (projectiles, their fragments and pieces of broken weapons) in the body/bones.

34.3.5 Determination of Stature

34.3.5.1 Long bones

Forensic Anthropologists mainly use the principle that the height of a person is directly related to the lengths of various bones. They have developed multiplying factors for most of the bones useful for the purpose. The standard error for each result is taken into consideration. The bones usually utilised and their multiplying factors are given below:

Table 34.6

Height Determination

S. No.	Bone length (B)	Multiplier factor (F)	B x F	Constant (K)	±Standard Error (O)	Stature Height S=(BXF+K) ± O
1.	Humerus (H)	3.26	3.26H	62.10	±4.43	3.26H ± 4.43
2.	Radius (R)	3.42	3.42R	81.56	±4.30	3.42R ± 4.30
3.	Ulna (U)	3.26	3.26U	78.9	±4.42	3.26U ± 4.30

34.3.5.2 Complete Skeleton

If a complete or near-complete skeleton is the exhibit, the bones are laid in the order they are present in the body and its length is measured. Flesh and skin factor (**~35 cm**) is added to get the height of the live person.

It may be noted:

- The long bones are in pairs (on the left and right sides), lengths for calculations are taken as the averages of the two in each set, whenever they are available.
- Usually, heights are given in limits: upper limit is with positive standard error and the lower limit is with negative standard error.
- The long bones are measured on a standard osteometric board for accuracy.

The estimation of height is fairly accurate most of the time, in competent hands.

34.3.6 Identity of the Victim

Earlier, the most crucial aspect of a Forensic Anthropologist's work was to identify a victim from his skeleton remains. In most of the cases, it was an uphill task. It is not so now. The following modes and methods and pieces of evidence help them to establish the identity:

1. **DNA Profiling:** has brought in a revolution in the identification of the dead from the skeletal remains, bones, and even their fragments. Nuclear DNA is often available. Mitochondrial DNA is usually available even in old bones (*supra*). When DNA profiling is available anthropological identification acts as corroborative evidence only.
2. **Fractures:** all fractures are unique. If a person has suffered a fracture in his lifetime, it structural form continues even after death on the skeletal remains, even after it is healed. It permits identification of the person if the original X-rays record is available. Comparison of the record with the fractures (healed or otherwise) indicates the identity of the deceased.

   A completely charred body was recovered from the debris of a burnt house which was occupied by a single owner. It was suspected that the body belonged to the owner.

   The owner was known to have suicidal tendencies. A few years earlier, he had attempted suicide with a firearm. A Radiograph was taken. It indicated several small fragments of projectile lodged inside the body. The fragments were not taken out.

   A Radiograph of the charred remains was taken. It indicated all those fragments in the body at relevant positions. It identified the deceased. (CH)
3. **Deformity:** any bone deformity in any body part of the victim can help to identify him from his skeletal remains. Deformities of head, legs, arms and neck are characteristic. A careful study of the same leads to the identity of the deceased.

   A few years ago, a skeleton was recovered from pit. Its identity had to be established. It was sent to a medico-legal expert. The expert discovered thickening of the neck bone on one side. He concluded that the deceased had deformity on the neck. The head remained tilted to one side. The information led to the identity of the deceased. (CH)
4. **Diseases:** certain bone diseases affect bone structures. If the skeletal remains show depredation of disease, it fixes (or excludes) the identity. A lifetime radiographs of the affected bone established the identity.
5. **Skull Superimposition:** it was frequently used for the identification of the deceased. Identifications from the 1:1 skull transparency (photograph) and life-size photographs of the suspected victim are made by superimposing the transparency over the life-size photographs of the head of the deceased. The positions of the nose, eyes, ears and chin should correspond. The superimposition (or non-superimposition) indicates the identity or non-identity of the suspect.

The use of computers has facilitated the manipulation of photographs (size adjustment, angle corrections, colour and contrast) and high quality evidence is thus produced and presented in the courts.

Three youngsters visited Morni hills, near Chandigarh. They took drinks and drugs. Late in the evening they had an altercation and one of the youngsters was strangulated by the other two. The dead body was thrown in the ravines, which ordinarily nobody visits. The skeleton of the body was discovered after a long time. Its identity via-a-vis the boy was established through skull superimposition. (CH)

The following anthropometric measurements of the actual skull, life-size photograph and ante-mortem life-size photograph of the person are taken and superimposed *inter se.* The following features help to establish a match or non-match:

- Total face height
- Face width
- Upper face width
- Lower face width
- Nasal aperture; height width
- Intra orbital width
- Orbital height, width

Seventeen persons were killed in a house collapse in Delhi, a few years ago. It was suspected that vibrations of generator caused the collapse. The bodies of the remnants of 16 persons were identified. The remnants of 17th person remained unidentified. They closed the case after a few months. The intelligence bureau, however, continued to investigate. They found that one of the terrorists was missing from the date of occurrence of this collapse. Were the remains of the seventeenth person of the terrorist? They wanted to check.

Skull superimposition technique identified the remnants to be that of the missing terrorist.

Presence of RDX in that debris established that the house collapse was due to an explosion, not due to generator vibration as first suspected. (CH)

In comparison of facial features of ante-mortem life-size photograph, skull morphology of the skull the following points are measured and compared:

- Eyebrows,
- Medial margins of the slit,
- Lateral margin of eyes,
- Position of moustache,
- Position of closed mouth,
- Face outline,
- Nasion,
- Position of the ear,
- Position of nostrils,
- Height of nose,
- Width of the nose,
- Width of mouth,
- Maximum width of nasal bridge, and
- Lip height.

In the famous Ruxton case, the superimposition of transparency of skull over the photographs was utilized for the first time. The technique proved useful in the differentiation and identification of the two murdered women.

The technique has been extensively modified and exploited since then. (CH)

A few years ago, an inmate escaped from a mental hospital. A thorough search of nearby localities proved futile.

After about a year, a skeleton was recovered from a jungle about 10 miles away from the mental institution. The remains of the clothes indicated that the deceased was an inmate of the mental hospital.

Several patients had run away from the hospital during the past few years. The dental charts were, therefore, checked and compared with the denture of the recovered skeleton. The comparison indicated that the deceased was probably the above referred patient.

The identity of the deceased was further strengthened through a radiograph of the spinal vertebrae, taken in the hospital before the patient escaped from the hospital. It corresponded with the vertebrae of the skeleton. (CH)

6. **Face Reconstruction:** there are two methods of reconstruction of face from a skull. In one, clay is used to cover the skull or cast and the "skin" is coloured according to the suspected victim's skin colour. A Forensic Anthropologist works along with a sculptor and an artist. The shape, size and colour of nose, ears and hair have to be guessed.

   In the second method, computer is used for Facial Reconstruction. The technique needs:

   - A 3-D scan of the skull,
   - A CT scan of the head of a similarly built person, and
   - Special software in the computer to manipulate 3-D images and CT pictures.

   The computer face reconstructions are becoming popular and they are being improved continuously. They are likely to obviate the use of clay technique.

7. **Post-mortem Interval:** Determination of post mortem interval, from the human skeletal remains, is a hard nut to crack for Forensic Anthropologists. There are innumerable variables that affect the post-mortem changes in a human body especially after it is reduced to a skeleton. Prominent variables among them are:

   (a) **Confinement place:** kept in a box, closet or other closed compartments, basement, almirah. or buried. Or; thrown in open: jungle, desert, ravine, hill or mountain side or, given a watery grave where fish and other water fauna change the remains.

   (b) **Fauna of the place:** microorganism, insects, rodents, animal and beast. They destroy or change the body remains. Or, scatter them.

   (c) **Soil characteristics:** acidity of the soil hastens the deterioration of bones.

   (d) **Environment:** temperature, humidity of the place may hasten or retard the changes. Snow preserves body.

   But post-mortem interval is an important entity. Forensic Anthropologists try to find answer to the question. In USA, the scientists are studying the Post-mortem Interval in a big way. They have created a Body Farm where the dead bodies are kept under observations and their conditions are studied at regular intervals. The researches should prove useful for the task. If the body is thrown or buried with clothes on, the rotting of the clothes also provide estimate of the time of death. In addition to the quality of the apparel, the usual factors (environmental climate, soil, fauna of the place!) affect the rotting of the clothes. The interval will vary from one climate zone to another zone.

8. **Ethnicity (Ancestry, Race):** a lot of research has been done and is being done to ascertain ethnicity of the skeletal remains as it is not only a discriminating feature in the identification process but it also promotes correct identification of sex. Interbreeding among the races has made racial discrimination a difficult task except in determining the ethnicity of the aborigines and in some tribes where there is not much interbreeding.

Anthropologists have described the main ethnic groups:

1. Caucasoid (narrow face and chin, long nose!),
2. Mongoloid,
3. Negroids (broad face, wide nose)
4. Australoids and
5. Polynesians.

Perhaps this is an exercise in futility! It is said that there are more variations in intra-racial group than in inter-racial groups.

34.4 PRESENTATION

Forensic Anthropologist presents their findings in the form of a report, oral presentation; or through both modes. In his presentation, he strives to:

1. Give complete inventory of the exhibits he had examined and identifies them in the court.
2. Use simple words (no jargons!), easily intelligible to an ordinary educated person.
3. Ensure that the report is free from double interpretation and ambiguities.
4. Base his finding on adequate data,
5. Inform about the tools and the techniques used.
6. Indicate, briefly, the salient features of his experiments, observations, data and inferences.
7. Discuss negative evidence and justifies its exclusion.
8. Give clear, concise, precise and intelligible conclusions.

34.6 SUPREME COURT CASES

(21st Century)

34.6.1 Forensic Anthropology in Action[7]

Author's Summary

The prosecution case is that the culprits murdered the victim by exploding a crude bomb and threw the body, later recovered by the police as bones and skull. A medico-legal expert identified them as those of the victim. The defense expert opined that the evidence was not sufficient to fix the identity of the deceased.

The high Court finding variance in expert evidence and taking into account the limited damage by the explosion acquitted the accused and remarked it is not safe to convict persons on murder charge when neither the identity of the victim is not proved nor it is established that the death was homicidal. The SC concurred with HC.

It is unfortunate that HC did not ask for DNA test for identity.

Highlights italicised

7. *State of Andhra Pradesh v Karanam Balarama Krishna Murthy*, JT 2002 (10) SC 551; Bench per Umesh Banerjee and Shivraj V. Patil JJ, [DOJ: 23 October 2002.

5. Before proceeding further in the matter, a brief factual aspect as found in the prosecution case may be adverted to at this juncture. On 30 June 1987 at about 8.30 p.m. at Jampanivari Cheruvu all the five accused persons had formed an unlawful assembly in furtherance of the common object, they had murdered one Nallapaneni Venkata Subbaiah by exploding country made bombs. The dead body was said to have been taken away and thrown somewhere by them. All the five accused persons had denied their guilt, but four out of five were found guilty and convicted and sentenced as aforesaid. The remaining one was acquitted.

6. Peculiarity is the hallmark in the matter under consideration as regards the prosecution case, since beyond a certain point there is no evidence available on record excepting the opinion evidence of a medical practitioner. Significantly, the body of Nallapaneni Venkata Subbaiah was not recovered but what was recovered were certain bones together with the remnant of a skull The prosecution case obviously hinges strictly on the opinion evidence of one Dr. K Krishna Reddy (PW-20) wherein it has been stated as below:

My opinion regarding this case is:

1. The bones belonging to human being.
2. From the evidences present on the skull and mandible and 1st concave vertebrae it can be said that the bones belong to a male individual.
3. The evidence present on the spinal column, skull and mandible it is possible to say that the age of the individual would be about 40-45 years, but the fact cannot be confirmed authentically.
4. The stature of the individual cannot be given.
5. Since there is no duplication of bones, it cannot be disagreed that they belong to single individual, but the same fact cannot be confirmed as there were no articular surfaces to the bones.
6. There were no signs of ante-mortem injuries or haemorrhage.
7. There were no signs of ante-mortem of post-mortem burns.
8. *The identity of the individual can be established from the absence of right 1st molar teeth in the lower jaw as it had fallen off years back and its cavity was filled by calcification completely. The left three molars of the lower jaw might have fallen off long back at least a minimum of 2 to 3 years.*
9. Time since death is about 2 to 3 months.
10. The cause of death cannot be given as there were no positive evidence.

Exhibit P. 15 is the certificate given by me. The contents mentioned in the report exhibit P. 45 are correct. After reading the report, I can identify the skeletal remains which I examine, if they are shown to me. M.Os. 1, 2, 8 and 10 are the skeletal remains that were sent to me for post-mortem examination. (Exhibit P. 45 marked because the accused has no objection in marking the same).

7. Significantly, we have on the record another piece of evidence tendered by one Dr. D Govindaiah (PW. 25) wherein the witness stated as below:

The skeletal remains were received by me in two stages. One set of bones were received by me on 26-10-1987. Another set of bones were received by me on 19-11-1988. I examined which those were received by me on 19-11-1988. I examined those skeletal remains and gave the certificate, opinion and the details of my examination by me as well as conclusions for the opinion. The following are the conclusions, opinion of my examination with respect to the above said skeletal remains.

1) *The anatomical configuration of all the bones were consistent with that of human bones.*
2) *It was possible to say that the age of the individual was about 50 years though the age estimation from the skull bones was variable.*
3) *The sex of the individual was male.*
4) *It was possible to say from the examination of all available bones that they belong to a single and same individual.*
5) *The stature that is the height of the individual could not be calculated as there was no single long bone intact without any post-mortem destruction by animals.*

8. The cause of death could not be determined from the available bones as there were no ante-mortem injuries to them.

9. All the long bones only show post-mortem destruction by animals by gnawing and eating at their particular ends. It was possible to say from the study and nature of destruction and presence of canine holes that the damage has been caused by canine animal's *viz.*, "dogs and foxes.

The evidence of experts thus vary in its evidentiary effect. The issue thus arises whether it would be otherwise safe to convict four persons under section 302 of the Indian Penal Code with punishment for life imprisonment or not. The criminal jurisprudence of the country requires us to reach more or less a certainty without which it would be well neigh impossible to convict a person. As noticed above, is it safe or otherwise risky to convict on the state of evidence available to the court by the two medical professionals. The High Court, however, answered the same in the negative.

10. *In its order the High Court was pleased to record the following:*

There were no signs or evidence of

(I) There was no direct evidence to prove that the deceased Naliapanenj Venkata Subbaiah died on 30-6-1987.

(II) The dead body was not recovered.

(III) The FIR was lodged on the next day at about 8.15 a.m....in a nearby police station without any reasonable explanation for the delay and without any indication as regards the death or nature of death of the deceased Nallapaneni Venkata Subbaiah.

(IV) The time or place of occurrence have been delightfully left vacant though the informant claimed to be an eye-witness.

11. It is this state of evidence led by the prosecutor which stands very severely criticised by the High Court and consequently recorded the following:

No offence under section 302 of the Indian Penal Code can be made out without proving that the victim under consideration was dead and that the death was homicidal in nature. In the present case, the prosecution has utterly failed to prove either of them and, therefore, all the appellants in the first two appeals are entitled to acquittal of the charge under section 302 IPC.

12. Needless to record that the High Court also has acquitted the accused persons under section 201 of the Indian Penal Code as well.

13. Mr. G Prabhakar, learned standing counsel for the State of Andhra Pradesh rather emphatically contended that by reason of the evidence available on record, question of having an order of acquittal would not arise in the matter at all. He has been rather emphatic as regards the reliance on the evidence of Dr. K Krishna Reddy (PW-20). While it is true that one of the doctors did opine that in fact the skull matches with the bones but the selfsame doctor as noticed above did say that as a matter of fact it is not possible to authentically state that the bones belong to one person.

14. Mr. Sushil Kumar learned senior counsel appearing in support of the appeals arising out of special leave petition (criminal) Nos. 3578-3580 of 1994 contended in the similar vein as by the state counsel, Mr. G Prabhakar, and supported the case of the prosecution. Mr. Sushil Kumar's attempt to impress upon the court that on the wake of the evidence of Dr. D Govindaiah, the question of acquittal would not arise.

15. *The acceptance of evidence of Dr. Krishna Reddy can be had in the event, however, the same is otherwise creditworthy. On the one hand, it has been stated that the factum of the bones of single individual cannot be confirmed as there were no articular surfaces to the bones but on the next breath, the witness goes on to clarify that there is in fact identity of the skeleton remains with the bones. As noticed above, the High Court did not think it fit to rely thereupon as it would be rather risky to depend thereon for the purposes of having a conviction under section 302 of the Indian Penal Code. We also do think it fit to record our concurrence therewith. The evidence stands out to be too shaky and weak on which reliance cannot be placed in the matter presently under consideration.*

16. Incidentally, the High Court has also in paragraph 4 of the judgment recorded its disagreement with the prosecution case as regards the applicability of section 3 of the Explosive Substances Act. We do feel it expedient to record our concurrence therewith as well by reason of the fact that the injuries on the person were superficial in nature and could not be said to be as a result of any bomb explosion and no vehicle or any other property could also be proved to have been damaged as a result of such a bomb attack.

34.6.2 Identity of Scattered Body Parts[8]

2. The facts of this case are very shocking and very distressing. Murder is committed of a young boy, the only son of his parents, who at the relevant time was studying for a medical degree. The manner in which he was killed and his dead body was disposed of after cutting it into different pieces was very gruesome and ghastly. The person in the dock and who was accused of the crime was another senior student in the same campus.

3. Brief relevant facts leading to the registration of the first information report and giving rise to the present appeal are being set out hereunder.

4. In the academic year of 1995–1996 the respondent-accused was studying in the senior first year course of MBBS and the deceased Navarasu, son of Dr. PK Ponnusamy (PW-1), a retired Vice-Chancellor of Madras University, was studying in the junior first year course of MBBS in Raja Muthiah Medical College, Annamalai University, Annamalai Nagar. The respondent was staying in Room No. 95 in E-1, Malligai Hostel belonging to the same medical college campus.

5. P.W-1 returned from his foreign trip on 7 November 1996 and was waiting for the arrival of his son Navarasu from college to celebrate Diwali which in that relevant year fell on 10 November 1996. When Navarasu did not return home till 9 November 1996, PW-1 started enquiring from the friends of his son, available at Madras but no information of his whereabouts could be gathered by the father. PW-1 then on 9 November 1996 rang up the university authorities to find out and ascertain the whereabouts of his son. When he was informed that the college authority found his hostel room locked and when it was broken upon, it was found that his belongings along with a small box were lying in the room but he was not available in the room.

6. The college authorities and the father were of the opinion that Navarasu had not left for Diwali to Madras, PW-1 thereafter rushed to the university on 10 November 1996 and made a complaint of missing of his son at about 11.30 p.m. on 10 November 1996 which was registered as Crime No. 509 of 1996 (Ext P-1).

7. While this process was going on and without the knowledge of Annamalai Nagar Police, a torso was recovered at about 8.30 a.m. on 7 November 1996 by G Boopathy, Inspector of Police, E-5 Pattinapakkam (PW-55), from PTC Bus-Depot at Mandaiveli Madras based on the information given by Prakash (PW-53), conductor of the bus. Route No. 21-G. The said recovered torso was sent for post-mortem after inquest.

8. Annamalai Nagar Police after registering the missing report started investigation and during the course of such investigation gathered materials and also received information from various persons including students of the college pointing the guilt towards the accused, who was also found absconding from the college premises from 12 November 1996 to 14 November 1996.

9. On 14-11-1996 the accused surrendered himself before the Judicial Magistrate, Mannargudi. The message of his surrender was conveyed to Annamalai Nagar Police Station, which got the police custody of the accused for five days from 18 November 1996. On 19 November 1996 at about 1.30 a.m. the accused gave a confessional statement stating that he has put the severed head of the deceased in the boat canal within the university campus. Pursuant to the said confession, the head was also recovered, Annamalai Nagar Police Station on 20 November 1996 asked E-5, Pattinapakkam Police Station for sending the records connected with the torso recovered at Madras on the suspicion that it may belong to the severed head of the deceased Navarasu, which was recovered at the instance of the accused Dr. K. Ravindran (PW-66) conducted autopsy/post-mortem of the head at 10.00 a.m. on 21-11-1996.

10. On 22 November 1996 a message was received from Villupuram Control Room which was forwarded to Annamalai Nagar Police Station which mentioned that three human bones femur, Tibia and fibula have been recovered at 1.30 a.m. on 21 November 1996 from the seashore of Konimedu of Merkanam based on the information given by the Village Administrative Officer concerned, Nagarajan (PW-43). Post-mortem of the limbs were conducted by Dr. Srinivasan (PW-45) and later, the limbs were sent to PW-66.

8. *Inspector of Police, Tamil Nadu v John David*, 2011 AIR SCW 2764 : (2011) 5 SCC 509 : 2011 Cr LJ 3366.

11. PW-66 after examining the severed head, the torso and three human bones abovementioned, found that there are scientific materials to hold that they belong to a single individual and also the fact that they belong to deceased Navarasu. The father (PW-1) of the deceased and Thandeeswaran (PW-60), nephew of PW-1, also identified and confirmed that the head and torso are of the deceased. For confirming the said fact, the blood samples of PW-1 and his wife Baby Ponnuamy (mother of Navarasu) were examined by Dr. G.V. Rao (PW-77) at Hyderabad by DNA test. PW-77 compared the tissues taken from the severed head, torso and limbs and on scientific analysis he found that the same gene found in the blood of PW-1 and Baby Ponnuamy, was found in the recovered parts of the body and that therefore they should belong to the only missing son of PW-1.

58. In the instant case, the fact that the severed head of the deceased Navarasu was recovered from the specific place which was indicated and identified by the accused, the recovery of other material objects at the indication/instance of the accused creates/generates enough incriminating evidence against him and makes such part of the confessional statement clearly admissible in evidence. The fact that the skull found in the water canal of the university belonged to Navarasu, deceased is proved from the evidence of Dr. Ravindran (PW-66), Dr. Venkataraman (PW-52) and G.V. Rao (PW-77).

59. PW-66 in his evidence has stated that the deceased appears to have died because of decapitation by injuries and that the injury is ante-mortem. The doctor also opined that a sharp cutting weapon would have been used for causing injuries. He further stated in his evidence that severing of head and removal of the muscles and nerve of limbs could have been one by MOs 9 to 11. PW-66 also opined that both the torso and head belonged to one and the same person.

60. Also from the evidence of Dr. Venkataraman (PW-52), Parasu Dental Clinic, Adyar, Madras it is found that he had given silver filling on the right upper first molar of the deceased and that he had removed the left upper milk tooth and removed the root thereof and the said fact was also clearly and rightly found in the post-mortem conducted by PW-66 on the head recovered from the boat canal. The said fact was also proved from the DNA test conducted by PW-77. PW-77 had compared the tissues taken from the severed head, torso and limbs and on the scientific analysis he has found that the same gene found in the blood of PW-1 and Baby Ponnusamy was found in the recovered parts of the body and that therefore they should belong to the only missing son of PW-1.

61. In the present case, the trial court relied upon the superimposition process/test made by Dr. Jayaprakash (PW-65), Assistant Director. Forensic Science Department, Madras, who stated in his evidence that the skull recovered was of Navarasu. Therefore from the evidence of PWs 65 and 66 it becomes amply clear that the skull recovered from the boat canal is of Navarasu only.

74. *Therefore, in our considered opinion prosecution has established its case on the basis of strong and cogent circumstantial evidence and that on the basis of the circumstances proved, there cannot be any other possible or plausible view favouring the accused. The view taken by the High Court is totally erroneous and outcome of misreading and misinterpreting the evidence on record.*

CHAPTER 35

FORENSIC ODONTOLOGY

SYNOPSIS

35.1 General 1621
35.1.1 Definition 1621
35.1.2 Application 1622

35.1 GENERAL

35.1.1 Definition

Forensic Odontology is a branch of Forensic Science dealing with teeth and marks left by teeth to identify criminal suspects or the remains of a dead person.

Forensic Odontology is also known as Forensic Dentistry. It is the application of dental (dentistry, Odontology) science in the dissemination of justice. In common parlance, it is the application of systematically organised knowledge relating to dentition, teeth, changes in them due to age, disease, accident, use or abuse, bite marks and artificial dentures in criminal investigation and trials.

35.1.2 Application

The main uses of Forensic Odontology include:

1. Identification of human remains (unidentified corpses, skeletons, skulls or dentures) from their denture.
2. Linkage of bite marks with the culprit in sexual abuse of females, children, spouses, imbecile persons and sometimes senior citizen. If a female has resisted the offender, she may bite the offender. The bite mark can link the culprit with the assault.
3. Determination of age of children/adolescents/young/old persons.
4. Determine if the subject is a minor or adult.
5. Identification of victims in mass disaster/mass graves.
6. Discrimination of bite marks whether they are of human origin or from the animal kingdom.
7. Reconstruction of the profile of the victim from the skeletal remains.

Dentures, teeth and teeth marks are often met within forensic situations where it is important to ascertain their source, to fix the identity of the source person, pet or wild beast: victim or perpetrator of a crime. Or, it is simply its application of Forensic Odontology to establish the identity of the person whose remains have been found; to identify a person who has lost memory, forgotten his identity, unable to recognise his near and dear ones and even does not know the place to which he belongs due to mental illness. Determination of age of a living person, corpse or skeleton also forms part of Odontology. It assumes great importance in some cases of murders, rapes and juvenile delinquency.

35.1.3 Background

It was known from time immemorial that teeth patterns of some persons are different from those of others. Such persons, with some prominent peculiar teeth pattern, colour tooth (teeth), diseased or missing tooth (teeth), odd extra tooth and uncommon structures of teeth could be distinguished from their teeth alone. But it did not amount to much and not used in Forensics. It was an odd identification from a limited group of persons. The need for such identification of persons was limited. Forensic Odontology (without the name) remained dormant for ages. The science has been named as Forensic Odontology. It is a new tool for the dissemination of justice. The demand for the expertise is increasing with the passage of time.

There is no doubt that the teeth pattern of each individual is unique. That is, it is different from that of any other person, including his or her parents, brothers, sisters, sons and daughters. Surprisingly, nobody has provided any experimental or statistical proof thereof. Nor, it must be appreciated; anybody has found the teeth of two persons alike. It is believed that the universal Law of Individuality holds which states that everything in this universe is unique. So are the tooth, dentures and teeth bites. No two teeth patterns, like fingerprints, of two different individuals, are alike.

Forensic Odontology is not being used extensively in India. It does not form part of the all forensics institutions, medical/dental colleges/departments. If a case comes up, it goes to:

1. A Dentist
2. A Forensic Pathologist
3. A Forensic Biologist
4. A Forensic Anthropologist

None of the institutions has developed the needed expertise. Consequently, the results are not satisfactory. It is hoped that Forensic Odontology is developed in the near future to help the criminal justice system. It may form part of dental colleges to start with and later become part of the major forensic institutions when the need for the expertise grows.

35.2 IMPORTANCE

Forensic Odontology has great potential in the criminal justice system. There is increasing awareness of its utility among the concerned persons. The availability, permanency, definite nature of the evidence in most of the cases where it is involved is its Hallmarks. It can reveal and tackle heinous crimes, sordid criminals and their *modus operandi*. Its need is bound to increase in the coming times.

35.2.1 Definite Identity

Like fingerprints, odontology provides definite identity (or elimination) of a corpse if the dental record (a dental cast(s), X-ray radiograph of the suspect's denture or the dentist's recordings) is available.

Definite identity is based on the numerous identifying characteristics, easily discernible: (~ 30 to 70) in various individuals' dentitions, their teeth orientation and in their repairs and treatment. They confer uniqueness to the dentition of a person. The prominent features, leading to individuality, are:

- The architecture of the dentition including roots,
- Position, size and shape of an abnormal additional tooth (teeth), if any,
- The dimensions of the dentures, teeth and roots,
- Inter-distances among the teeth *inter se,*
- Orientation of the teeth *inter se,*
- Twisted and tilted teeth,
- The number of teeth present originally and surviving healthy teeth at the given time. Disease, accident or hereditary factors and life style have different toll in different persons. The particular positions and the characteristic shapes identify the common source,
- The number and position of the missing, broken and diseased teeth,
- Wear and tear of the teeth,
- Extractions, and
- Repairs: fillings, materials used for filling, crowning, capping, root canal treatment, bridges, implants.

In Canada, a serial killer, infamous as "The Vampire Rapist", Wayne C Boden, had raped and killed many females during 1969–1971. His *modus operandi* included the biting of the breasts of the victims, which ultimately led to his conviction. He left no other tangible evidence at the scene or on the victim.

The investigating officer requested the local Odontologist to examine and compare the bite marks with the dentures of the suspect. He carried out the examination and consulted other experts from Canada and abroad. He demonstrated to the judge and jury ***29 matching points*** in Boden's denture and in the bite marks on the body of the last victim. The judge and the jury accepted his findings and convicted him on the sole evidence of bite marks. He was sentenced to life imprisonment.

It was the first case in North America where the conviction was based upon bite marks alone. (CH)

35.2.2 High Profile Crimes

Forensic odontology is involved in high profile crimes:

1. Murders, mass murders, kidnappings.
2. Sex crimes especially rape, gang rapes, sodomy, child abuse, spouse abuse, sometimes followed by murders and then hiding or destroying the evidence through burning, burial, dismembering the body, throwing it in secluded places or in water bodies where it may be discovered after years.
3. Dentition (and dental evidence) is long-lasting, almost permanent for all practical purposes. It can help the identification of the victim even after decades. Thus, the evidence is superior to even fingerprint evidence in permanency. Fingerprints are destroyed comparatively easily. The skin is eaten by the insects or putrefies!
4. It is possible to build a Post-mortem Dental Profile from the dentition taken from the disfigured body or skeletal remains. A thorough examination can provide the following information about the profile under favourable conditions:
   - DNA profile,
   - Age,
   - Sex,
   - Ancestry,
   - Occupation,
   - Dietary habits,
   - Smoker or non-smoker,
   - Drunkard or drug addict, and
   - Socio-economic status of the subject.
5. Forensic Odontology expertise can easily be organised. The normal dentist (odontologist) can pick up the expertise, if he so desires, after some specialised training.
6. Bite marks are found in many criminal cases. They link the criminal in many a case, but not in all cases. In some famous cases, the Forensic Odontologists have found ample evidence to get the culprits convicted on bite marks alone. However, in cases where bite marks fail to provide linkage, the saliva in and around the marks, if available, can identify the culprit via DNA profiling irrefutably.

35.3 NATURE

Forensic Odontology is classified into three main categories for the study of the subject more conveniently:

1. Identification of the living, the dead, the skeletal remains or the body remnants where dentition (or its parts) are available as identifying clues
2. The identification of bite marks and the biter
3. Determination of age

The three main branches of Forensic Odontology involve dentition, teeth, jaws (mandible and maxilla) mainly. They are the main source of evidence. It is, therefore, worthwhile to have a bird's eye view of their architecture.

35.3.1 Dentition, Teeth

The human teeth (20 in children and 32 in adults) are located (fixed) in the two jaws: mandible and maxilla in equal numbers (16 each). Teeth in each jaw are in the form of an arch. Each set is called dentition.

There are two classes of teeth: milk teeth and permanent teeth. Milk teeth start erupting at the age of about six months and the other at the age of about six years. The eruption of both types of teeth gives some idea about the age of the person.

The teeth are of four types: incisors, canine, premolar and molar.

35.3.2 Milk teeth

Milk teeth are also known as temporary or deciduous teeth. The maximum number of these teeth is usually 20, ten on the upper jaw and ten on the lower jaw. The ten teeth on each jaw are:

- Molars = 4
- Canines = 2
- Incisors = 4

The cavity formations for housing the teeth start from the 3rd or 4th month of pregnancy. The teeth start appearing in about six months' time after birth and eruption of milk teeth is complete in about two years. The following table gives a general idea of the eruption/shedding time of the milk teeth:

Table 35.1

Primary Tooth Development

S. No	Eruption time	Shedding time
Upper Teeth		
Central incisor	8-12 months	6-7 years
Lateral incisor	9-13 months	7-8 years
Canine	16-22 months	10-12 years
First molar	13-19 months	9-11 years
Second molar	25-33 months	10-12 years
Lower Teeth		
Second molar	23-31 months	10-12 years
First molar	14-18 months	9-11 years
Canine	17-23 months	9-12 years
Lateral incisor	10-16 months	7-8 years
Central incisor	6-10 months	6-7 years

35.3.3 Permanent Teeth

Permanent teeth start erupting usually in the fifth or sixth year. There are 32 permanent teeth. Sixteen of them are in the upper jaw (maxilla) and even number in the lower jaw (mandible). The sub-classification of the sixteen teeth in each jaw is:

- Incisors = 4
- Canines = 2
- Pre Molars = 4
- Molar = 6

Table[1] 35.2

Number and Numbering of Various Teeth

Teeth	Number	Assigned numbers in Upper Jaw	Assigned numbers in Lower Jaw
Incisors	4+4	7, 8, 9, 10	23, 24, 25, 26
Canine	2+2	6, 11	22, 27
Premolar	4+4	4, 5, 12, 13	20, 21, 27, 28
Molar	6+6	1, 2, 3, 14, 15, 16	17, 18, 19, 30, 31, 32

The permanent teeth of the human dentitions are given 1 to 32 numbers. There are various systems in numbering; the above being one of them. They are divided into four segments, the numbering and the divisions take the following form:

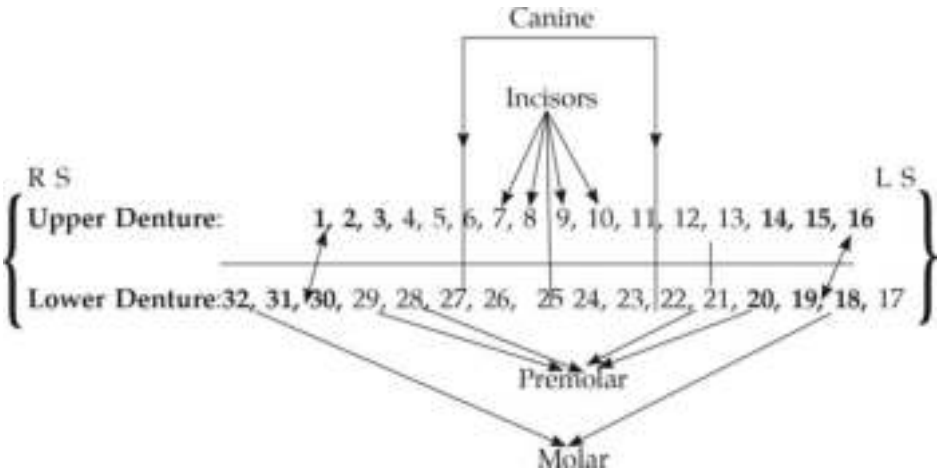

Fig. 35.1

Graphic Display of Teeth Architecture

1. American Universal Numbering System has been used in numbering the teeth.

35.3.4 Tooth Architecture

A tooth has the following important parts:

35.3.4.1 The Crown

It is the top part of the tooth. It is covered by hard enamel, which is white in colour unless some disease or dental hygiene neglect gives it some colour. As it is very hard, it withstands a lot of use or abuse in chewing and biting. The morphology of the crown and its surface characteristics provide identifying features of the bite marks.

35.3.4.2 The Root

The root of a tooth is covered by gums. It is embedded in the jaws. Canine, incisors and premolars have usually one root though in rare cases, canines and premolars may have two roots. Molars have two or more roots.

Roots have varying shapes, sizes and orientations *inter se*. They also vary from person to person. They provide significant differentiating features for identification.

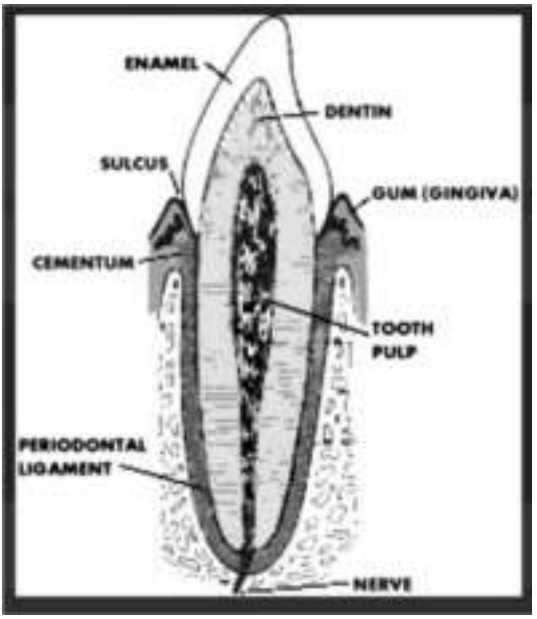

Fig. 35.2

Root of a tooth

35.3.4.3 The cavity

All tooth roots have cavities. They are also called root canals. They are filled with pulp and are connected to blood vessels through a nerve called root canal nerve. The root canal treatment and fillings provide discriminatory evidence. The pulp provides body cells for DNA profiling.

35.3.4.4 Saliva

The DNA identification has made the matters easy. The culprit is bound to leave saliva stains in and around the bite marks in all cases of bites, which provides foolproof identification or exclusion of suspect as culprit. But saliva is not always available. If the body is thrown in a

water body or the stain is washed off in a heavy downpour, DNA profiling is not possible. In such cases, only Forensic Odontology provides the needed evidence.

Saliva is not a specific constituent of Odontology. But it is an inseparable part of all teeth in the living being. It is transferred from the teeth (or through lips) to the bite mark site and is always there until removed by natural elements or otherwise. It can individualise the biter and decides the involvement or exclusion of a suspect "beyond reasonable doubt".

In fact, after the induction of DNA analysis in Forensics, saliva in or around the bite marks has assumed tremendous importance in the identification of the biter. It is believed that in the coming times DNA analysis alone would be used to fix the culprit's identity in those cases where saliva is available. Bite mark patterns will continue to rule the roost where the saliva is washed off or removed.

Teeth marks, in bites, are not clear many a time. DNA profiling via saliva, from the bite marks, will finish the uncertainty[2] in those cases where the marks are incomplete or unclear.

35.4 PRACTICAL POLICE WORK

Location, Collection, Preservation, dispatch and transport of the evidence to the Forensic expert is Practical Police Work (PPW), carried out by law enforcement agencies or by private investigators. It is essential that the investigating officer understands the basic principles and follows a set protocol to collect maximum and correct clues and information to ensure successful investigations.

They follow the general crime investigative pattern, yet because of the newness of Forensic Odontology and high complexity of bite mark collection and identification, the investigator needs a Forensic Odontologist to collect the bite marks correctly.

35.4.1 Basic Principles

1. The identity (*vis-a-vis* the crime), authenticity, integrity and continuity of the chain of possession of the evidence seized must remain beyond reasonable doubt, through proper documentation and, whenever possible, though eyewitnesses. Proper inventory on the label tag, properly secured (sealed!) packaged and movement log of the evidence go a long way to maintain the identity and integrity of the evidentiary clues.
2. All actions (seizure, processing, movement and storage) taken *vis-à-vis* the evidentiary clue must be properly recorded for later verifications, if required.
3. An average investigating officer has neither the basic knowledge nor the training, nor any practical experience worth the name to handle or process bite marks evidence. He needs the help of a competent Forensic Odontologist. The **S**pecial **I**nvestigation **T**eam (**SIT**) should have a Forensic Anthropologist to ensure proper collection of the evidence. SIT should consist of:
    - **Chief Investigator:** He is the team chief. He should be an experienced police officer. He will have the over-all responsibility to assemble the desired team (also additional manpower in cases like mass murders or disasters), collect the necessary tools, assign duties to the team members and oversee that the team, individually and collectively performs their duties efficiently and competently. He writes a report on the examination of the scene of occurrence after completing its examination.

2. In 2009, a member of the American Boards of Forensic Odontology surveyed the Bite mark identification cases. He found that the positive reports furnished by the Forensic Odontologists were wrong in 63% of the cases.

- **Documentation Officer:** He has to be a technician of high order to document the work done at the scene. Photographic and video coverage of the scene and the evidence thereon is his main task. Preparation of site plan, sketches of the scene, including evidence thereon and recording the scene and the evidence may be his additional duties.

  Sometimes the services of a draftsman are requisitioned for preparing the site plan, especially in expansive and important scenes like those in mass murders or disasters. Software has come up which can draw a 3-dimensional sketch.

  Textual descriptive documentation is essential part of documentation. The chief investigator writes the notes himself.
- **Forensic Odontologist:** He guides technical aspects of seizure, collection and preservation of dental evidence. He is indispensable. In mass murders and disasters, more than one Forensic Odontologist may be needed.
- **Forensic Pathologist:** Massive death scenes like mass murders, mass disasters or extensive wide ranging fires also needs Forensic Pathologist(s) and other doctors.

35.4.2 Scene of Occurrence

The handling of the scene of occurrence (crime scene) has been discussed in some details earlier[3]. Here the crime scene or disaster scene where Forensic Odontology plays important role has been discussed briefly.

1. Mass Murders: there are numerous mutilated bodies in mass murders. Their identification is not only a social responsibility but it is also a legal requirement. The investigating officer has to do all the legwork. The ultimate identification has to done by the Forensic Odontologist.

> *In Twin Tower Trade Centre explosion (New York, (2001) about twenty % of the 973 mutilated bodies were identified through Forensic Odontology.* (CH)

2. Mass Disasters: Air accidents, rail accidents, road accidents, landslides, earthquakes and other natural disasters (Tsunami!) occur every other year. The processing of these scenes is also one of the primary duties of police. There are often mutilated bodies at the scenes of occurrences. Forensic Odontology helps the police to identify them.

> *In Tsunami disaster (2005) most of the mutilated bodies were identified through Forensic Odontology.* (CH)

3. Mass Graves: When a large number of persons are killed or die together, they are often buried together, in big mass grave(s). Later the necessity to identify a person(s) from the skeletons in the grave may arise. The dentitions of the skeletons are examined and compared with dentures or dental data collected from the dentists of the suspected person(s). The evaluations link/de-link the skeleton to the suspect if proper dental record is available.

> *The body of the Adolf Hitler was buried along with about a dozen persons. It became essential to identify his body remains to make sure that he was dead as there were rumours that he had escaped and fled to South America and that the suicide news was inspired and false. The bodies (in boxes) were exhumed and his body remains were identified through his dental record (available with his dentist) which was unique.* (CH)

The other sites where Forensic Odontology evidence is found, include the following prominent sites:

1. Graves in graveyards
2. Burial sites

3. See: Chapter 4 of this book.

3. The secluded site where the body was disposed
4. Wells and pits
5. Ponds and canals
6. Homes (basements, walls, compounds), hotels and houses

   Laila Khan, an actor, and her family had been missing since February, 2011. Police had not been able to make head or tail of their whereabouts.

   On 10 July 2012, while searching the farmhouse of Laila, the police came across two water pits, in the compound of the house. The pits were covered with earth. Digging of the two pits unearthed six skeletons!

   The skeletons were supposed to be that of Laila and her family. DNA profiling, the better method than Odontology, was used to identify them. (CH)
7. Trains, buses and cars

35.4.3 Evidentiary Clues

Forensic Odontology evidentiary clues are generally limited. Most of them are:

1. Dentitions,
2. Teeth,
3. Repairs and restorations,
4. Fillings,
5. Bridges,
6. Root canal treatment,
7. Implants,
8. Bite Marks,
9. Saliva, saliva stains,
10. Artificial Dentures,
11. Casts,
12. Dental Radiographs,
13. Dental Records,
14. Dental eruptions,
15. Dental Ossification, and
16. Dental pulp.

The first ten items are found on the culprits, victims, dead bodies or skeletons or their remains; as the case may be. The last six items are usually found with the subject's dentist.

The sources for evidentiary clues are:

1. Live human beings
2. Dead bodies; at various stages of putrefaction/burning/mutilated bodies/ dismembered bodies.
3. Skeletal remains, skulls, dentures alone; anywhere and everywhere
4. Pets (in pet bite cases),

5. Odontologists' clinic(s): dental records, radiographs and casts of the dentures (partial or full) are found in the subject's dental clinic.

35.4.4 Bites on Dead or Live Body

If the teeth pierce the skin at the bite site of a live person, the injury bleeds. If the bite is inflicted on a dead person after the blood has settled, the injury normally does not bleed. However, if the bite is soon after death it bleeds to a varying extent.

The handling of the live, injured, dead bodies or skeletal remains is part of investigating officer work. It has also been discussed elsewhere[4]. The main task, however, is the processing of the dental evidence.

35.4.5 Action Protocol

The lead investigator plans, guides, controls and monitors the action protocol. The clue materials have to be located, collected, preserved, packed, transported, stored and evaluated. The steps are taken in such a way, as mentioned earlier, that their relevancy, identity, integrity, authenticity, continuity of the chain of custody is preserved and that legal formalities are observed in letter and spirit so that the courts do not question the validity and legitimacy of the evidence and reject it. The action protocol follows the general guidelines given in the chapter on "Scene of Occurrence and in Investigation of Death".

35.4.6 Standard Dental Data

The investigating officer takes the following steps to collect ante-mortem data (the standard data) for comparison:

1. Study the list and Portrait Parle of the missing persons of the nearby areas.
2. Get rough data from the expert (forensic Anthropologist!) about the age, sex, height and built of the person whose remains are being examined.
3. Compare the generated data with that of the missing person(s) and make a reasonable guess about the possible person(s).
4. Ascertain the dentist who has been treating the guessed missing person(s).
5. Collect the anti-mortem dental data (written record, radiographs and dental casts) of the subject from the dentist who had provided the dental care.
6. The anti-mortem evidential materials and data are standards for comparison. They are seized observing all the legal formalities and kept in a way to maintain their identity, integrity, authenticity and continuity of chain of custody.
7. Submit the collected questioned and standard (anti-mortem) data to the Forensic Odontologist. Associate the concerned family dentist with the forensic odontologist to evaluate and compare the data from two sources, if possible.
8. Obtain the report and submit it to the court when the identity of the person is established.

35.5 FORENSIC ODONTOLOGIST

An ideal Forensic Odontologist (also known as forensic Dentist) is a person:

4. See chapter 23 of this book.

1. Who is educated in dentistry, has been trained in Forensic Odontology, is engaged in the case and research work in Forensic Odontology or related subject(s) and has published papers to his credit.
2. Who has been initiated to the speciality through training and attachment for considerable time to a renowned and experienced Forensic Odontologist in a respected dental institution where Forensic Odontology work is routine.
3. Who has acquired ample practical experience in Forensic Odontology during his attachment period, and later.
4. Who is interested in the field and takes up the professional challenges seriously.
5. Who has no preconceived idea about the outcome of the examination. He starts examination with open mind. Collects both positive and negative data and goes by the preponderance of the data.
6. Who furnishes his reports on the basis of adequate data, for which minimal is fixed by the professional community.
7. Who informs the court about the tools and techniques used and indicate the salient observations of the work.
8. Who generates the data using the latest proven and well-established tools and techniques, being used and accepted by fellow professional in the field.
9. Who abides by the standards recognised (or prescribed) by his professional fraternity.
10. who does not accept the dictates of intuition, hunch or supernatural revelations.
11. Who remains a man of science. His inferences flow from the observations he made during the examination.
12. Who has no enemy to punish and no friends to save.
13. Who is immune to temptation, influence and bias.
14. Who is aware of the Conformational Syndrome[5], considers it and avoids it scrupulously.
15. Who has a liaison with Forensic Pathologists, Forensic Anthropologists and fellow Forensic Odontologists. He consults them in all refractory and borderline cases.
16. Who writes a report in simple and easily intelligible language not amenable to double meaning or ambiguity.
17. Who writes clear and unambiguous conclusion fall in one of the following categories:
    - Positive (±)
    - Probable (±)
    - No report data insufficient!

35.5.1 The Expertise

Forensic Odontology can be divided into following categories for the convenience of study and evaluations:

1. Evaluation of dentition, dentures, teeth
2. Identification of bite marks and their linkage with the biter.
3. Determination of age from the study of teeth
4. Developing the subject's Profile.

5. It is conscious or unconscious desire of the expert, to prove what has been suggested to him by the referral authorities.

35.5.2 Evaluations

Forensic Odontologist is doing a Yeoman's job in the identification of persons from corpses, skeletal remains and bones. The exhibits may be of drowned, burned, dismembered bodies found in varied situations, including those in mass murders and mass disasters like Tsunami, fires, or buried skeletons (or parts thereof), bodies thrown in wells or pits, bodies or their parts from abandoned bodies in deserted places like ravines, jungles, deserts.

The science has come a long way since it started identifying skeleton remains. Today it is one of the important major tasks of the Forensic Odontologist. He often succeeds to give definite identification of the deceased if the ante-mortem dental data of the possible suspect(s) is available. Dentition perhaps provides the most frequent and certain type of evidence to identify skeletal remains. The process is laborious but highly rewarding. The Forensic Odontologist carries out the following drill:

1. Examines, photographs, X-rays, sketches, prepares casts/dentures/transparencies and takes detailed notes of the questioned evidence: dentition, tooth or combination of teeth.
2. Prepares positive casts from the negative casts procured from the dentist to compare the positive casts with the questioned dentition.
3. He prepares transparencies for comparison. Superimposition comparisons are effective to prove match or non-match of the dentition.
4. He generates complete dental profile chart of the questioned dentition and includes all the identifying features of each tooth, the pattern of the teeth and of the dentition as a whole.
5. He procures the ante-mortem dental data (Standard data) of the suspect(s). It includes written notes, sketches, dental casts, dentures (partial or complete, experimental or final) and details of the dental work done, with dates from the subject's dentist via the police.

   The SIT chief obtains the dental data from the subject's dentist with or without the help of a Forensic Odontologist.
6. Compares the prepared dental profile from the available dentition and other generated data with the data from the dentist's record, tooth-by-tooth, corresponding combinations of teeth and dentition. The preponderance of the alike or non-alike features decides identity or exclusion of the suspected person.
7. He consults the subject's family dentist and other specialists in the field, whenever possible. This is a **"must"** in refractory and borderline cases.
8. He accounts for oddities, if any.
9. Writes a lucid, unambiguous and intelligible report and conclusions about his finding.

There is no fixed number of matching points in Forensic Odontology identifications. The nature of the evidence is such that even one malformed or broken or repaired tooth may provide clinching evidence. It is equally possible that the whole dentition may not provide adequate evidence to furnish definite opinion. The latter proposition is rather rare.

Identification of a person via dentition and teeth has proved useful in a variety of situations:

35.5.2.1 Confirmation of Death

Confirmation of death is often needed to settle property matters and to meet the ends of justice in cases of fugitives from the law. A dead person is beyond law. Hitler's case of confirmation of his death is an outstanding international example.

Adolf Hitler was the chief warlord of the IInd World War. Millions of people died in that war. Ultimately, the Allies defeated him. They thought Hitler was responsible for the Genocide of more than six million persons. They wanted to try him for the war crimes. However, he was not available! Some thought that he had run away. Other said he has committed suicide.

According to the suicide theory, Adolf Hitler committed suicide along with his wife Eva Braun On 30 April 1945. He ingested a cyanide capsule and shot himself in the right temple with his pistol. The bodies of both the persons were later (as per his instructions) burnt with petrol just outside his bunker. The fire did not consume the bodies completely. The unburnt parts, therefore, were buried in a nearby jungle.

The staff of Hitler spread the news of suicide. However, not many believed them. It was rumoured that he was in hiding and might strike back in due course. The Allies wanted proof of his death.

Russian forces had reached Hitler's bunker first. They investigated. The bodies were exhumed. The dental record of Hitler was procured from his dentist. It was compared with the denture recovered from the burnt body. There was ample evidence to fix the identity of Hitler from the remains. Specifically, the clinching evidence was:

- *A gold bridge with porcelain facets in the upper jaw*
- *Two bridges in the lower jaw*
- *Presence and absence of teeth in the lower jaw*
- *The dentist provided the corresponding evidence from his records.*

The evidence finally made the Russians believe that "Hitler is dead". It took some more time for the rest of the Allies to believe the same. (CH)

35.5.2.2 Identifications in Mass Disasters

Mass disasters like earthquakes, aeroplane accidents, train accidents, fires in congested cities take a heavy toll of life. Quite a few persons are mutilated so much that they cannot be identified. Forensic Odontology comes handy to identify them if they have dental record.

Tsunami waves of 2005 killed thousands of persons in Asia. More than 800 odd victims were extensively disfigured, mutilated and dismembered. Their kith and kin could not identify them. Forensic Odontologist identified 90% of the disfigured bodies through dentitions and their records with the dentists. (CH)

35.5.2.3 Mass Murders

Terrorists all over the world commit mass murders. They use various modes: bombing, sabotage (exploding Kanishka aeroplane!), arson, shooting sprees, gas chambers, and rail and road accidents to commit mass murders. In mass murders often some of the bodies are mutilated beyond normal recognition. Forensic Odontology provides the needed identification by identifying the dentition of the mutilated victim.

Terrorists used novel technique to blast the World Trade Centre's twin towers in USA. No explosive of the usual type was used. Instead, two aeroplanes, fully fuelled struck the towers. Huge fire started and the building collapsed. 2996 persons were killed. More than 6,000 others were wounded.

973 bodies were highly disfigured and could not be identified in the usual way. Forensic Odontology could identify 20% of 973 bodies. (CH)

In mass murders and mass disasters, the number of police personnel, volunteers, and hired labour and of dental specialists is very important. The team leader coordinates the work of all the persons. The working drill takes the following pattern:

1. Provide medical assistance (First Aid) to the injured and send him to the nearest hospital without delay.
2. When a dead body is recovered, he takes the following action:
   - Gets death confirmed from a doctor.
   - Gives it a serial number for identification, which should continue until the body is claimed by the relatives or it is disposed off otherwise.
   - Records Portrait Parle of the deceased.
   - Wraps the body in a white sheet and place it in a safe place where the relative can see and identify the body.
   - Ensures correct identification of the body and records the identifying data.
   - Hands over the unidentified bodies to the Forensic Odontologist's team.
   - Provides the team with details of the possible persons with dental data whenever possible.
   - Preserves the dead bodies in cold rooms until identified or ordered disposal by the competent authority.

35.5.2.4 Mental patient

Sometimes the mental patients escape from mental asylums. They, sometimes, die incognito. There bodies or skeleton are discovered long after death. They are often identified through their dentitions.

Some years ago an inmate of a mental hospital escaped from the hospital. Extensive searches in the nearby localities were made but he could not be located.

After about a year, the skeleton of a person was found in a jungle. The torn clothes found around the skeleton could be identified to be those of the inmates of the mental hospital. It was believed that the skeleton was that of a mental patient from the hospital. However, during the last few years quite a few inmates had escaped. Therefore, the identity of the person whose skeletal remains were available had to be established on firm grounds.

The last escapee had a dental record in the hospital. It was compared with the dentition found on the skeleton. It matched. The identity of the deceased was established.

The identity was confirmed further by comparing the vertebra of the skeleton with the radiograph of the vertebra taken in the hospital earlier. (CH)

35.5.2.5 Miscellaneous

Forensic Odontology has proved useful in the dissemination of justice in many other ways. It helps to:

1. Identify persons who have lost their memories,
2. Determine the age of a person,
3. Ascertain the social background of a person,
4. Determine the race, and
5. Identify the teeth marks on non-human surface.

In a case of murder, there were scratch teeth marks on the butt of the firearm of a suspect. Forensic Odontologist identified them to be the teeth marks of the murder victim. The evidence linked the suspect with the murder. (CH)

35.6 AGE DETERMINATIONS

The determination of age of a person: alive, dead or of skeletal remains is an important ontological task. It helps in:

1. Profiling a person from dental remains,
2. Elimination of possible victims in mass murders or disasters,
3. Exclusion (or inclusion) of a missing person in the list of dead persons,
4. Determination of major/minor status of an offender.

The following factors help to determine the age of a person:

- Eruptions of teeth
- Developments of teeth
- Deterioration of the denture/teeth

Some aspects of these factors are discussed briefly here.

35.6.1 Eruptions of Teeth

The determination of the age of a person from the dentition is based upon eruption of teeth, which starts at the age of six months and continues up to the age of 21 years, with some individual variations. They, therefore, do not permit determination of the exact age of the person from teeth eruption. An idea of an approximate can be gathered from the tables.

Table 35.3

Eruption Schedule of Milk Teeth

S.No	Tooth	Age of appearance (in months)	
		Lower jaw	Upper jaw
1.	Central Incisor	6	7-8
2.	Side Incisor	7	9
3.	I Molar	12	14
4.	Canine	16	18
5.	II Molar	20	24

Permanent teeth replace them in due course. They pushed out the milk teeth and take their place. The eruption period of the permanent teeth in the adolescent (and youth) is given in the following table 4:

Table 35.4

Eruption Schedule of Permanent Teeth

S.No	Tooth	Age of appearance (in years)	
		Lower jaw	Upper jaw
1.	Central Incisor	6-7	7-8
2.	Internal incisor	7-8	8-9
3.	Canine	9-10	11-12
4.	I Premolar	10-12	10-11
5.	II Premolar	11-12	10-12
6.	I Molar	6-7	6-7
7.	II molar	11-13	12-13
8.	III molar	17-21	17-21

35.6.2 Teeth Development

Teeth development has extensively been used to determine the age of adults from twenty-one years of age onwards. Numerous factors in the development of teeth morphology help to estimate the age of live or dead persons; or, their skeletal remains. They are highly complex. With proper inputs, however, Forensic Odontology can provide a close estimate of the age. Details of the tools and techniques used by the specialists are too technical to be discussed in this discourse. The main modes are, however, mentioned below:

1. Completion of dentition
2. Completion stage of roots (erupted teeth!)
3. Rate of formation of enamel
4. Attrition of the crown
5. Formation of cementum
6. Transparency of root dentin
7. Root surface re-sorption
8. Discolouration and staining of teeth
9. Changes in the chemical composition of teeth

Forensic Odontologist, given the time and can arrive at close estimates.

35.6.3 Age of Foetus and Infant

The Forensic Odontologist faces the problem of the determination of age of a foetus or infant in cases of adultery and abortions.

The age of the foetus or infant can be estimated with great accuracy. The teeth formation process (mineralisation) starts during appropriate stages of foetal development. Primary (baby) teeth start to form between the sixth and eighth week of prenatal development, and permanent teeth begin to form in the twentieth week. The age determination is facilitated by:

1. Histological
2. Radiography
3. Detection of neonatal lines, present on deciduous and permanent teeth.

Using these and other methods (Stack's Regression lines!) a competent Forensic Odontologist can give the age of the foetus.

35.7 BITE MARKS[6]

Bite marks, as the name indicates, are 3-dimensional impressions or 2-dimensional surface prints, which are created by the bites of human/animal/beasts. The marks may be on food articles, chewing gum or the human body, wood, leather or on other surfaces. They may also create sliding marks.

6. British Association for Forensic Odontology has issued comprehensive guidelines for bite mark investigation and analysis.

The identification that the given marks are human bite marks is often possible as they are in the form of an arch corresponding to the dentition arch. That they are of one or more persons can also be determined in most of the cases. However, linking the culprit and the bite marks *inter se* is not always possible from Forensic Odontology because of many variables, including the topography of the surface and the mechanics of the biting process and the force used for their creation. However as saliva is deposited along with the marks, DNA analysis of saliva identifies the biter. In USA, in some case, where the biter was identified via odontology were found to be wrong identifications via DNA profiling. If DNA material is found along the mark, it is used for identification of the biter.

> *Roy Brown, of New York State, USA, was convicted for murder mainly on the basis of bite marks which, according to the Forensic Odontologist had come from Roy Brown. Later, on comparison of DNA profile of the saliva deposited around the bite marks with the DNA profile of Roy brown, it was found that the DNA profiles differed. The convicted person was acquitted! (CH)*

The linkage of the biter to the bite marks is important in almost all cases of sex crime, murders and other violent crimes hence they are processed with extra care. The processing, in all cases, offers a serious challenge to the investigating officer who should pass it on to the Forensic Odontologist.

The shapes, sizes and orientations of the marks, individually (one tooth) or collectively (two or more teeth) are highly characteristic. They permit the identification of human bite and link them to the biter.

The above case indicates that to error is possible. But can we afford, in Forensics, such errors which affect the lives and liberties of a person?

Bite Marks occur quite frequently in sex crimes including sex murders. They may also occur in other crimes like theft, scuffle, fighting, assault, child abuse and homicide. A person may also create false bite marks to accuse another person of assault. Dog bites, beast bites and animal bite also come up for investigation sometimes.

Bite marks identification is the real tough bite for the Forensic Odontologist. There are so many variables involved in the biting process that the replication of bite marks of the same person on the same strata is difficult to achieve.

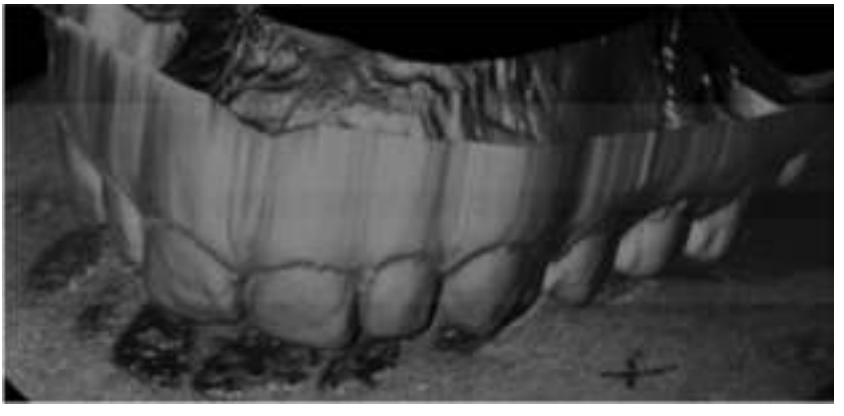

Fig. 35.3

Do the bite marks and the teeth correspond? exceptional correspondence!

Biggar sex-murder case was a blind murder that took place in a small town of Scotland in 1967. The body of a fifteen-year-old girl, Linda Peacock was found in a cemetery of the town. The girl was found not only strangled to death but was also beaten and bitten. The only substantial evidence found on the person of the deceased or at the scene was a fairly well-defined bite mark on the breast of the deceased. The police took the body to a forensic Odontologist. He, after careful observations, found that the bite marks on the deceased had certain peculiarities which could fix the source of the bite mark. He collected the evidence through photographs (numerous) and cast. The police investigations revealed that the deceased was the girl from a nearby village and nobody had seen her in the town before except on that day.

The police, after taking all the aspects of the case into consideration, came to the conclusion that the girl had been brought to the place by someone who killed her later. They also felt that the person was probably an inmate from the detention house or a student of the local college.

There were only teeth marks to identify and pin the crime on the culprit. They decided to take and took dental casts of all the inmates of the detention house and students of the college.

There were thus dental casts from about four hundred persons. The Odontologists started the examination of the casts and their comparison with the bite marks.

Most of them were eliminated easily; a few needed more careful examination for elimination. Ultimately, only five casts were left for finalising the identity or non-identity of the questioned marks.

The expert had found a very peculiar feature in one of the teeth in the bite mark. There were two pits on the tooth due to a rare disease. These pits became the hallmark for the identification of the culprit. Similar pits were not found in the corresponding tooth in any other teeth of any of the four hundred persons except in the corresponding tooth of Gordon Hay.

A galaxy of British dentists and forensic pathologists including Professor Keith Simpson, studied the casts and decided the identity issue. They could finally come to the agreed conclusion that the bite marks on the person of the deceased had come from Gordon Hay, an inmate of the detention home and from no other person.

Some corroboratory evidence was also found.

It was the first case in UK, in which the main evidence was the bite mark only. The scientists therefore took extra precautions. The exhibits along with the opinion were sent to some experts in Scandinavian countries. They also, largely, agreed with the findings and furnished general support.

Gordon Hay's appeal to the superior court was rejected. (CH)

35.7.1 Bite Mark Variables

The main variables affecting the character of bite marks are:

1. The number, orientation, shape, size and sharpness of the teeth involved.
2. Elasticity of the skin
3. Variations in the bite marks of the same person

Fig. 35.4

Bite marks 1 and 2 from the same set of teeth. Duplicates never exactly alike

4. The mental and emotional state of the biter
5. The force and speed with which the victim was bitten.
6. The bite site.
7. The resistance offered by the victim.
8. The movement of the victim or the biter (of the bitten body parts) while biting.
9. The mutilation of the mark.
10. Natural changes in the marks with the passage of time.

A serious reason for incorrect opinions is Conformational Syndrome the Forensic Odontologists. It is the subconscious tendency of most of the experts (even of other expertise) to conform to the views of the investigator, first impression or his personal hunch. Expert's unconscious bias and ego "to prove" the given proposition is often responsible for the wrong opinion.

In view of so many variables, it is advisable to:

1. Engage only an ace Forensic Odontologist.
2. Use only the latest technology.
3. Consult/discuss the finding with another seasoned expert before the report is furnished.

Ted Bundy was a serial killer in USA. He had killed many a female in rape-cum murder assaults. In the last case he killed two women, injured three more. One of the victims, Lisa Levy was raped, battered and bitten.

She had two bite marks; one on the neck and the other on her left buttock. The latter was quite clear. It was properly photographed and the skin bearing the mark was excised and collected as crime exhibits.

The police had to get the impressions of the dentition of Ted Bundy through court orders as he refused to give impressions[7]. A Forensic Odontologist took numerous photographs of the front teeth from both the jaws. He found uneven teeth pattern which could help to identify the bite marks.

The Forensic Odontologist carried out the examination and comparison. He found ample evidence to show that the bite marks on Lisa Levy had come from the teeth of Ted Bundy.

- *The structural alignment corresponded.*
- *Chipping was similar and on the corresponding teeth.*
- *The size and structures of the bicuspids of the corresponding teeth were alike.*

The expert prepared the transparency to scale, and superimposed the same over the crime mark. The superimposition was quite impressive.

7. The police feared that Ted Bundy might grind his teeth to change the pattern. So, they kept a watch on him.

The expert showed that he had carried out a number of test matches to ascertain the validity of his tools and techniques. He had found them reliable.

The court called another far more experienced Forensic Odontologist. He confirmed the findings.

The court sentenced Ted Bundy to electric chair; more or less on Bite Mark evidence alone. (CH)

The identification of the biter from bite marks, in spite of a lot of progress in Forensic Odontology, still remains highly subjective. Computers have improved the situation; still it has remained a serious challenge to the specialist.

35.7.2 Identifying Features

In spite of the numerous variables (*supra*) bite marks are identified day in and day out. The identifying features are:

1. **The dentition arch**: it is usually 3 to 5 cm, creating corresponding arched shaped impression. It identifies that it is human bite and also help to eliminate some suspects.
2. **Presence of odd unique tooth:** (teeth); the unique teeth mark permit identification of the biter. In Biggar Murder case an odd feature on one tooth alone identified the biter.
3. **The layout, orientation, shapes and sizes:** of the teeth; leave a pattern of oddities in the bite marks which permit the identification of the biter.
4. **The interspaces and angularities of the teeth *inter se*:** they vary from one person to another. These variations are reflected in the bite marks and help to identify the biter.
5. **Wear patterns:** of teeth help identification
6. **The missing teeth**: their number, position, size are registered in the bite marks. They allow easy eliminations and help to identify the biter.
7. **The presence of broken/damaged tooth/teeth**: they often offer individualising evidence.in the identification of bite marks.
8. **The presence of additional/misaligned teeth (tooth);** they leave characteristic features in the bite marks, which help to identify the biter.
9. **Repaired, restored or artificial teeth**; they give individualistic patterns. They are highly significant in the identification of the bite marks.
10. **The deposition of saliva;** it takes place in and around the bite marks in all bite marks. DNA profile fixes the identity of the biter irrefutably.

DNA profiling of saliva, on bite marks, is preventing many miscarriages of justice which had been taking place due to incorrect linkages through bite marks (Roy brown case: *supra*). However, there are situations where saliva or its stain is not available. For example, bodies recovered from water or exposed to heavy rain may not retain saliva. Clever criminal may wash off the saliva and its stains or may substitute it with that of the victim, or some third person or even of animal (dog!). The Forensic Odontologist therefore, is indispensable in such cases.

The identification of the biter from bite marks, in spite of a lot of progress in Forensic Odontology, still remains highly subjective; though computers have improved the situation.

35.7.3 Bite Marks Collection

The Forensic Odontologist is the main person to locate, collect and preserve the marks for evaluation with the help of the investigator and the medico-legal expert. In the handling of the evidence, he has to:

1. Scrutinise whether the bite marks are of human or animal origin.
2. Collect saliva swabs from the bite marks.
3. Photograph the marks. Use high quality digital camera.
4. Departmental photographer often helps to:
   - Photograph the bite mark as it is found at the site, keeping in mind the postural and photographic distortions. Take additional photographs for postural correction and curved surfaces.
   - Take repeat photographs, placing two scales, at right angle to each other together, along with the case data chit in each shot.
   - Take additional similar shots at intervals of one day each until the bite marks fade. The bite marks change colour and there is also some change in the shape and size of the marks with the passage of time.
   - Take 1:1 transparencies and photographs for comparisons.
   - Takes 3 D photographs in those cases where the bite marks have depth and skin is torn.
5. Draw sketch of the bite marks as faithful to the original as possible.
6. Trace the bite marks on a transparent plastic sheet.
7. Take casts of the bite marks if they have appreciable depth.
8. Collect the skin (dermis and subcutaneous tissues) carrying the bite marks, if the bite marks are on a dead person.
9. Collect all the photographs taken by the medico-legal expert in the mortuary, by the IO at the Scene and those taken by the media people.

35.7.4 Action

The bite marks are usually on the body of the victim. The investigator notices them at the time of the examination of the body; and if the victim is dead, at the time of inquest. The marks may be easily visible, indistinct or covered with blood or clothes. Proper location, collection and preservation of the marks for further evaluation may need the help of the medico-legal expert and/or the Forensic Odontologist. In all cases of bite marks, he must requisition the help of these specialists.

35.7.4.1 Sites

The bite sites, in forensic situations, are found on various parts of the body:

1. **In sex or sex-murder cases;** the common sites are the cheeks, the breasts, the neck, shoulders, the arms, the buttocks of the females.
2. **In homosexual cases;** the bites are found on the back, shoulders and cheeks.
3. **In child abuse cases;** the most abused sites for bites are the cheeks and the arms.
4. **In defence bite cases;** the common sites are the hands and the arms. They are usually deep (3-dimensional) and they may also be sliding marks.
5. **In false self-inflicted bite marks; the** usual **bite mark sites are** arms, thighs, breasts. On asking, an accomplice may inflict bites on cheeks, breasts and/or buttocks.

35.7.4.2 Quality

The quality of the bite marks is often poor. They are not clear. The investigator may fail to identify whether the marks are bite marks or bruises in some cases. The rule of the thumb for their identification is that they are in the form of an arc of 3 to 5 cm. If the investigator finds such an arc; a Forensic Odontologist is asked to examine. He will ascertain its nature. In any case, whenever there is doubt about the nature of the mark, his expertise is utilised.

35.7.4.3 Collection of Bite Marks

It is better to collect the bite marks evidence is at the time of post-mortem examination if the victim is dead; or, at the time of medico-legal examination when the victim is alive. Forensic Odontologist, however, must participate in the collection of the evidence. The action protocol is to:

1. Ascertain if the marks are bite marks.
2. Ascertain if they are of human or animal origin.
3. Collect saliva swabs from the bite marks.
4. Photograph the bite mark as it is found at the site keeping in mind the postural and photographic distortions. Additional photographs may be taken for postural correction and curved surfaces.
5. Photograph them before and after cleaning.
6. Take repeat photographs. Include two scales, placed at a right angle to each other together and parallel to the lens. Also place a case data chit in each shot.
7. Take additional similar shots at intervals of one day each till the bite marks fade. The bite marks change colour and there is also some change in the shape and size of the marks with the passage of time.
8. Prepare 1:1 transparencies and photographs for comparisons.
9. Prepare a sketch of the bite marks as faithful to the original as possible.
10. Prepare a tracing of the bite marks on a transparent sheet.
11. Prepare casts of the bite marks if they have appreciable depth.
12. Take 3 D photographs in those cases where the bite marks have depth and skin is torn.
13. Collect the skin (dermis and subcutaneous tissues) carrying the bite marks if the victim is dead.
14. Collect all the photographs taken by the medico-legal expert in the mortuary or those taken at the scene.

Forensic Odontologist or a competent dentist collects the standard data for comparison from the suspect(s). The Odontologist follows a drill to:

1. Examine the suspect in the presence of a witness(es).
2. Collect saliva sample from the suspect.
3. Check the suspect for dental treatment and notes down the changes, in chronological order, if possible.
4. Carry out complete dental charting of the biting teeth.
5. Record the occlusions and surface characteristics of the biting teeth.

6. Take a number of photographs of teeth of the suspect from various angles.
7. Prepare 1 : 1 transparencies from the photographs for superimposition.
8. Prepare casts of both the dentitions preferably in Dental mass.
9. Obtain bite marks) on soft materials (like chewing gum) for preliminary check.
10. Obtains similar sliding marks on a hard object like wooden piece, plastic or metallic (Lead, Aluminium!) sheet, if the questioned teeth marks are in sliding form.

The Forensic Odontologist ensures identity, integrity, authenticity and continuity of the chain of possession.

35.7.5 Bite mark Identification Process

The Forensic Odontologist examines and compares the questioned and test marks without any preconceived ideas about the match, without bias and without any pressure. He takes into accounts the total evidence (distortions, movement and surface topography). The Forensic Odontologist evaluation is:

1. Assesses the factors which cause distortions in the bite marks
   - Bite site
   - Position of the assailant
   - Relative movement of the teeth and the bitten surface
   - Intervening clothes, if any, through which the victim has been bitten
   - Resistance of the victim
2. Examines, measures, and compare the dentition arch with the bite marks arch in respect of size, orientation and shape.
3. checks the correspondence (presence or absence) of teeth in the corresponding locations.
4. Compares the sizes, shapes and orientation of the standard and questioned marks.
5. Studies and compares the *inter se* gap pattern among the teeth.
6. Compares the surface characteristics of the teeth present in the two types of marks.
7. Locates and compares peculiarities in the topography of individual tooth mark or in a combination of teeth.
8. Uses clear and unambiguous 1 : 1 transparencies of the test marks for superimposition on the 1 : 1 photograph of the bite marks to show correct match.
9. Uses computers to show correspondence (or otherwise) through overlays of the photographs from the dentition and the bite marks.
10. Uses 3-D photography of the bite and test marks for better appreciation of the evidence.
11. Takes cast the denture of the suspect for better appreciation/ demonstration of the evidence.
12. Locates, assesses and accounts for the non-corresponding features in the marks.
13. Finalises the report after consultations/discussions with other experts.

35.8 REPORT

The Forensic Odontologist writes a concise, precise yet comprehensive report on the departmental report form. He mentions tools and techniques used, observations made, data generated and logical inferences out-flowing from the observations and data. He explains the ever-existing negative evidence.

His conclusions are clear and give one interpretation only, as already mentioned above.

35.8.1 Recent Advances

Forensic Odontology is making long strides to make it more useful in the dissemination of justice. Some of the major thrusts areas are:

35.8.1.1 Dentition Library[8]

Digitised dental record is being stored in computers like fingerprint records. The dentitions are being classified and the data is collected in digital form. Whenever there is a reference to the library with the dentition itself or with data about the questioned dentition recorded in the same way as done for the library, the data can indicate the possible identity of person(s) to whom the dentition belonged. In simple words, the dentition reveals the identity of the person. The building up of the data is yet in the initial stages, in USA. There is no corresponding project in India today.

35.8.1.2 DNA Profiling

Teeth carry DNA profiling material with them in the root canal pulp and it is retained for a long time even after death. It can be used for the identity of a person. If a broken tooth is left on the person of the victim or at the scene it can identify or excludes the identity of the suspect owner of the tooth irrefutably.

Mitochondrial DNA is found in the teeth bones. It can be utilised to identify the person from the skeletal remains of the body even after thousands of years.

Further, teeth of live person are always smeared with saliva. They deposit it on, around or in the bite mark. Saliva provides material for DNA profiling.

Pulp in the root canal is a useful source for DNA profiling and it can be used even after years for the purpose.

35.8.1.3 Induction of 3-D Photography[9]

Bite marks are sometimes 3-dimensional. They can be better appreciated and evaluated if they are recorded through 3-D photography. It has proved a valuable innovation in those cases where a Forensic Odontologist is not able to examine the bite marks in situ. 3-D photography is also a more effective way of presentation of evidence in courts. The judges can appreciate the evidence better.

35.8.1.4 Computers in Forensic Odontology[10]

The use of computers in the evaluation and presentation of Forensic Odontology evidence has facilitated the task of the Forensic Odontologist in many ways. Some of the important uses of computer in Forensic Odontology is being utilised are:

8. http://dgrc.org/dgo last accessed on November 2019.
9. Lewis, C. *et al.* 2004. Journal of Forensic Identifications, 52(4), 185 and Jour. For. Sci. 2005, 50(1).
10. Jour. For. Sci. 2002, 47(2), 354 (also see references in 12 above).

1. Dentition record Library
2. Automated search of dental data in dentition library, corresponding to the data generated from a dentition.
3. Identification of the questioned dentition through automated comparison of the data in library computers through Odonto Search software. The software has almost finished the subjective element in dentition data comparison. It gives the identification itself.
4. Creation of overlays of dental casts and their comparison with the photographs of the bite marks.
5. The bite marks photographs are often inadequate. They are being improved through computer enhancement and other software.

35.9 LIMITATIONS

Forensic Odontology is a new and emerging science in India. It is being used only in very few cases. There are reasons for its limited use.

1. Forensic Odontology is not known to many, even educate persons. Hence, they are not able to appreciate the evidence.
2. There are very few institutions, which teach, train, do research work or provide expertise in Forensic Odontology to the needy.
3. The expertise requires a lot of legwork on the part of police. There may be many suspects. The dental data may be with different dentists. He has not only to locate the suspects but has to go after the dentists of the area. It is time-consuming task, each time! They tend to avoid it whenever possible.
4. Indians are not dentist savvy. Nor most of the dentists maintain a proper dental record of their patients. Often the long trails (if the investigator takes up) end in fiasco! No standard data is found.
5. Bite mark identification via dentition is highly subjective. It involves so many variables that if the scientist deviates even slightly from the scientific path he meets his Waterloo. In short, eternal vigilance, expertise of high order, consultations with other professionals and ages of experience are needed for reliable results. Undoubtedly, it is a tall order for anyone.
6. Bite marks are fickle. They not only change with time but for a host of other reasons they are often variable. Each case of bite marks is a challenge to the scientist and a research project in itself.
7. Limitations of time and resources also limit the quality of the findings.

The agony of wrong identifications, in most of the bite mark cases, is alleviated by DNA profiling. However, in cases where no saliva or body cells are available identification via dentition is the only media.

Necrophagous carrion action

36.1 GENERAL

Forensic Entomology is the application of knowledge relating to arthropods in the dissemination of justice. It mostly involves insect-related evidence, which forms evidentiary clues in criminal (or civil) situations. The utility of the knowledge and its application had been known now for centuries. However, the imposing name "Forensic Entomology" and its extended uses were not prevalent.

Forensic Entomology, as a discipline, started in right earnest only in the 1970s. The scientists started using the knowledge about the necrophagous carrion action of insects on the dead bodies and rotting flesh to determine the time of death. It has become a respected part of forensic pathology. Researches added new dimensions to the expertise. Thus, Forensic Entomology is in fact "old wine in new bottles", with enlarged contents and with better tools and techniques. They have increased the confidence level in the evidence; covering a wider field and attracting more clientele, in consonance with similar developments in other fields of Forensics.

Incidentally, it is one of the oldest branches of Forensics. The first case in which it was used to make the culprit confess was in the thirteenth century.

> *The investigator of the case must have been a genius who used insects to identify the weapon of murder in the thirteenth century in China. The weapon, in turn, identified the murderer.*
>
> *The investigator was a Chinese magistrate. There was a murder in the rural area on a farm. A number of farm labourers had been engaged to harvest the paddy crop. One of them had murdered the victim who carried a number of sickle wounds.*
>
> *The magistrate investigator collected the sickles from all the workers. He placed them in the warm sunshine. Soon after, one of the sickles attracted flies, presumably due to the blood sticking to the sickle. As there was no blood on other sickles, flies did not visit them. The owner of the sickle was hauled up for murder, on the evidence provided by the flies*[1]*, he confessed to the crime.* (CH)

36.2 NATURE

Forensic Entomology is the scientific study of the invasion of the succession pattern of arthropods including insects, arachnids, centipedes, millipedes, and crustaceans with their developmental stages found on the decomposed cadavers found during legal investigations. It is the application and study of insects and other arthropod biology to criminal matters.

It is primarily associated with death investigations mainly to find the time of death; also called **P**ost-**M**ortem **I**nterval (PMI). However, it is also used to detect drugs and poisons, determine the location of an incident, and find the presence and time of the infliction of wounds.

In other words, Forensic Entomology utilises the entomological evidence, of arthropods, their life cycle, their habitat specificity, their seasonal emergence, their fragments and remains or the chemical content of the body remains, mainly for the purposes of law.

36.2.1 Classification

Forensic Entomology is classified into the following categories:

- Medico-legal Forensic Entomology
- General Forensic Entomology
- Urban Forensic Entomology
- Stored food-stuff Forensic Entomology.

1. Song Chi. 1247. From Wikipedia "*Forensic Entomology" Internet.*

36.2.1.1 Medico-legal Forensic Entomology

The Forensic Entomologists study the nature of the arthropods, their location in the body part, life cycles, faunal succession and the nature and composition of their remains at the scenes of murder, suicide, rape, physical abuse and drug trafficking. The study enables the Forensic experts in many ways, to answer various questions, which may come up during their medico-legal examinations. For example, it helps them to find out:

- The time of death, also called **P**ost-**M**ortem **I**nterval (PMI).
- The negligence shown to a child or incapacitated person.
- The exact site of the crime scene as many insects exhibit a degree of endemism[2]
- The season in which the victim killed/died
- Drug identification from the remains of the insects. The drug may have caused the death. The sub-branch is called **entomotoxicology.**

In India, medico-legal Forensic Entomology is utilised mostly to determine the post-mortem interval (**PMI**) but it is hoped that in the coming years its full potential is utilized to solve crimes.

36.2.1.2 General Forensic Entomology

General Forensic Entomology is based upon the fact that the arthropods vary tremendously with varying temperature, humidity, season and location. They have unique habitat characteristics. Further, the variety of species is legion (in millions)! Given the right tools and techniques and expertise, they can be linked to specific sites, individual flora and fauna, and to specific seasons and habitat. Thus, *inter alia,* they help to link the criminal with the crime, with the victim, with the changing scenes, with the weapon of offence. The branch plays important role in the dissemination of justice. Specifically, it helps to:

- Ascertain the place(s) where the corpse had been shifted from time to time from the original crime scene.
- Detect/identify the poison(s) used to kill the victim from the remains of insects.
- Find the area of origin of narcotics of plant origin in the narcotic material with that of the suspected site, which indicates the crime scene.
- Discriminate the real crime scene by comparing the fauna of the real crime scene and that on.
- Identify the victim from the sucked blood residues left by the fauna.

36.2.1.3 Urban Forensic Entomology

Urban Forensic Entomology is concerned mainly with the urban pest fauna which infests the buildings (kitchen and bathrooms), gardens. The pests are becoming a serious menace with increasing urbanisation. The fauna, mostly insects, feed on the organic waste, dead flesh and on the living being. They spread diseases and cause economic problems. Their evidence, both in civil and criminal cases, plays a crucial role; but the public being unaware, this field has so far remained unexploited in India.

Urban forensic Entomology is also concerned with appropriateness of certain pesticides and their applications to protect stored products, in order to safeguard the users of the food products.

2. They are location centred. They occur only at certain places/environment.

36.2.1.4 Food-Storage Forensic Entomology

Stored foodstuffs are often infested by insects which cause a substantial loss to the owner; the more serious problem, however, occurs when the owner pushes the infested products to an unsuspecting consumer, spreading diseases and even death. Forensic entomologist in such can provide expert help both in criminal and civil trials involving spoiled foodstuff. The speciality is yet to make its mark in India.

36.3 FORENSIC ENTOMOLOGICAL ARTHROPODS[3]

36.3.1 Arthropods

The number and nature of arthropods is legion. We discuss only those, which are encountered in Forensic Entomology. Flies and beetles are frequently involved for the evidence.

Forensic Entomology is mostly concerned with **insect** arthropods, more specifically with flies and beetles. Occasionally, scorpion or spider evidence may also figure but it is rare. The discussion in this chapter is, therefore, limited to insects only, especially to those insects which are frequently involved in their various avatars in evidential situations. They are mostly necrophagous carrion arthropods (insects). They eat flesh and other rotten organic matter.

Each of these insects has a large number of sub-types, which vary with varying habitat and environment. Temperatures and humidity are important determiners. They are thus site-specific, time-specific and environment-specific clues that help the Forensic Entomologist to link them with the place of their origin, the season and the time at which they appear on a corpse where they are found.

The nature of Forensic Entomological evidence is varied and complicated. Relevant evidence is discussed under the following categories:

- Arthropod fauna
- Life cycle (Metamorphosis) of fly
- Faunal Succession Table; the order in which insects feed on a corpse is known as faunal succession.
- Faunal remains
- Entomotoxicological clues

36.3.1.1 Arthropod Fauna

The population of the arthropod fauna, being site-variant (place-specific), environmental variant and time variant (season-specific) varies with each place and time. The season variance ensures that the insect found on the body will correspond to the season in which the corpse has come into existence. The environmental conditions affect the growth of the insects and the succession table. Thus, the variables help to fix the site and the time and it also gives idea about the environments under which the corpse had been kept. In other words, it indicates the season and the time of the occurrence and the place or places where the corpse had been lying, kept or stored. The information unravels the events in the occurrence.

The arthropods, as already mentioned, are mostly necrophagous (corpse-eating) and are particularly relevant to medico-legal entomological investigations. The variations of the insects in each category due to varying environment further discriminate the evidence.

3. Any invertebrate of the phylum arthropoda having a segmented body, jointed limbs, and usually a chitinous shell that under goes moulting, including the insects spiders and other arachnids, crustaceans and myriapods.

36.3.1.1.1 Flies

Flies constitute ninety percent of the arthropods. They are found almost everywhere. The variety of flies is very large. They are the first on the scene. They prefer a moist corpse for the maggots to feed on, as such a corpse is easier for them to chew.

Flies have a strong sense of smell. They can smell blood and rotting flesh from a long distance. They are often the first to locate the dead. They prefer a moist corpse for their offspring (maggots) to feed on. The most significant types of flies are:

Blowflies:

They are also known as Cluster, Blue bottle, Green bottle or Black blowflies. This fly is about one cm long. Its body is in three segments. There are more than a thousand species of the fly in the world. The typical habitat for blowflies is temperate to tropical area. They prefer soft damp soil and litter. In such an environment larvae thrive and pupate.

Hatching from an egg to the first larval stage takes from eight hours to one day. Its development has three stages, called I instars, II instars and III instars. Each stage is separated by moulting event.

The forensic importance of this fly is that it is the first insect to reach the carrion at the scene because of the extraordinary sense of smell for the dead, from a long distance.

Flesh Flies:

Most of the species of flesh flies live and breed on flesh, dung, or decaying material. They have black and grey longitudinal stripes on the thorax. Some species lay their eggs in the gaping wounds. Other species give birth to live young flesh fly on dead bodies of humans and animals, at all stages of decomposition.

Housefly:

The housefly is the most common fly found in homes. It is known as the carrier of disease germs and infects people and food articles. The whole body of the housefly is covered with hair. On the thorax it has four longitudinal dark lines on the back. The underside abdomen is yellow. It lays about 500 eggs in batches of 75 to 150 eggs each. Hydrotaea species is of particular forensic importance.

The various stages of development of the fly family which help in forensic investigations are:

The Housefly:

It is about 8-12 mm long. It has two wings, two red eyes. The thorax is grey and is covered with four blackish lines. The body is covered with hair-like projections. The life span is about 2 to 4 weeks. It does not survive in the cold.

1. **The Eggs:** the eggs are found in clusters of about 75-150 eggs, on debris or rotting organic matter. They are about 1-2 mm long and are white in colour. They survive for about one day. Then they change to maggots (larvae).
2. **Maggots (larvae):** Instar I, II and III are various stages of growth of the maggots before they change into pupae. The life span of the maggot is more than one week. They are pale yellow in colour and about 3-9 mm long. They feed on rotten organic materials and are voracious eaters.
3. **Pupae:** They emerge from the III-instar maggots. They are about 8 mm long and are reddish brown in colour. The flies come from the pupae in about one week.

36.3.1.1.2 Beetles

Beetles are generally found on the corpse when it is more decomposed. In drier conditions, the moths replace beetles.

Beetles are seen on the corpse when the decomposition of the same is in an advanced stage. The common varieties of beetles met with in death cases are:

- Rove beetles
- Hister beetles
- Carrion beetles
- Hide beetles

The beetles have medico-legal importance because of their appearance after a specific period of death, their destruction of the maggots (they prefer to eat the maggots) because of their varied larval stages. Beetles usually lay eggs in the corpse itself. In some species the eggs take a long time to hatch into larvae. They usually appear on the cadavers in the advance stages of decomposition of the corpse, appearing at night most of the time and hiding under the corpse during the daytime.

They can live for a long time on the corpse.

Fig. 36.2
A beetle

36.3.1.1.3 Mites

Mites; there are many types of mites: they feed on a corpse. Some appear in the early stages of decomposition, while other mites feed on dry skin in the later stages of decomposition. If mites arrive at the corpse before any fly eggs hatch into maggots, they first eat the eggs, which delays maggot development. This may lead to incorrect PMI estimates.

Some beetles carry mites on their bodies, which feeds on fly eggs. If they arrive at the corpse before any fly eggs hatch into maggots, they eat the eggs. It delays maggot development. This may lead to incorrect PMI estimates.

36.3.1.1.4 Moths

Moths and butterflies are biologically related. Moths are almost the last visitors to the corpse assisting in its decomposition. The moth larvae feed on hair.

Moths feed on mammalian hair during their larval stages and may forage on any hair that remains. They are amongst the final arthropods contributing to the decomposition of a corpse.

36.3.1.1.5 Other arthropods

Other arthropods: are spiders, scorpions, wasps, ants, crabs, shrimps, myriapods (multi-legged creatures and live in the soil or in leaf debris).

Wasps, ants, and bees may feed on the body or may eat the insects feeding on the corpse during the early stages of decomposition. They may lay eggs, and the appearance of eggs and larvae on the body can mislead the Forensic experts to determine the post mortem interval (PMI).

In some countries, parents have used bees to punish their children to enforce discipline. They have also sometimes caused road accidents when they bite a person driving a vehicle. Forensic entomologists identify the sting marks in such cases.

The author has not come across even a single such case. However, the possibility of such cases cannot

36.3.2 Life Cycle (Metamorphosis) of a Fly

A fly is the first faunal visitor of the corpse. A housefly lays eggs on the available source, which may be garbage, faeces, wounds, sputum, spoiled food and dead matter including flesh. It lays about 500 eggs, in lots of about hundred (~75-150) eggs at one time. The eggs hatch in about 24 hours to give maggots (larvae). The larvae grow and pass through three stages:

[I Instars (1 day) ⟶ II Instars (2 days) ⟶ III Instars (4 days) ⟶ pupa]

Thus, in about a week's time the larva changes into a pupa, which, in turn, changes into a fly in about 10 days, leaving behind a puparia, the outer sheath of the larva. The fly is ready to mate in about two days. It lives for about a month.

Temperature and humidity play crucial roles in the life cycle (metamorphosis) of the fly.

(Life span ~ one month)

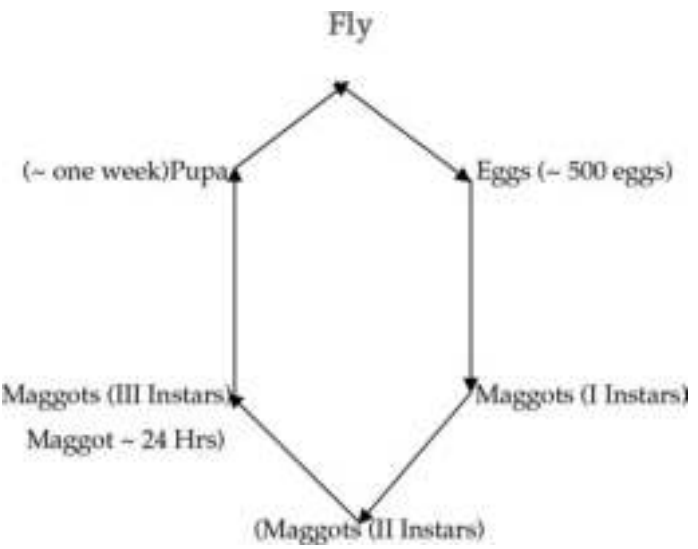

Fig. 36.3

Life Cycle of a Housefly

The above life cycle is for the common housefly, most common in necrophagous attacks. The lifecycles for other flies follow a similar pattern, though the details of the time element and their structures vary somewhat.

36.3.3 Faunal Succession Table

The order in which different insects or their products appear on a corpse is known as faunal succession. Faunal succession has been successfully utilised to get the most important information about the Post-Mortem Interval (PMI). Properly studied identification of the insects and their remains can lead the Forensic Entomologist to the five different stages of decompositions, which in turn can indicate the PMI. The five stages are:

1. Initial fresh stage; flies reach the corpse and start laying eggs in natural orifices or in the wounds.
2. Bloated stage
3. Initial active decomposition stage
4. Advanced decomposition stage
5. Dry remains of the corpse stage

The rough indicators of succession table are:

Presence of different species of flies, their eggs, maggots, larval stage, pupae, pupae moult and their co-presence indicate the succession. Flies are the first to reach a corpse.

House flies, flesh flies and blowflies are the common ones. The development of the larvae (length, weight) has also been used to find PMI.

1. The appearance of beetles and their eggs, larvae, pupae and young beetles; beetles usually appear on a corpse at an advanced stage of decomposition, often at the last stages of decomposition. They are easily seen as they have comparatively large sizes.
2. The identification of the species of mites helps to fix the PMI. Some species of the mites appear at early stages of decomposition. Some species of mites appear when the skin has dried.
3. Moths are the last visitors to the corpse. They feed on the hair of the corpse from all parts.

A number of factors condition the appearance of insects and other arthropods: temperature, humidity, environment, upkeep of the body and faunal access to the corpse, the destructive role of predatory insects and other creatures play their crucial roles. The Forensic Entomologist, therefore, has to be one with extensive experience not only in Forensic Entomology but also in the local fauna and environmental conditions. Otherwise, errors can vitiate the results.

36.3.4 Faunal Remains

The most important faunal remains are the moult of pupae[4], which it leaves when it comes out in the form of a fly. Its presence indicates that the insect had gone through its full life cycle. The fragments of flies are indicators of the species of the visitor and thus indicate the stage(s) of decomposition. The larvae of various stages of development are also useful indicators of the life cycle stage of the insect.

4. Cover shed by the pupa when it comes out as fly.

36.3.5 Entomotoxicological Clues

The remnants of insects including the flyspecks, regurgitated material and excreta are used as entomotoxicological clues. If the victim had died of poison, the poison will be found in the remnants of the insects. The analysis of the material can indicate qualitatively the nature of the poison. Modern instruments and techniques (chromatography!) can identify the poison.

36.4 IMPORTANCE

Forensic Entomology evidence is mostly corroboratory. In some cases, however, it has provided crucial evidence.

36.4.1 Time of Death

Forensic entomology provides useful method for determining **P**ost-**M**ortem **I**nterval (PMI) after about 3 days. It is accurate to a day or a range of days. In some cases, it may be the only method available to determine **P**ost-**M**ortem **I**nterval (PMI), elapsed time since death. The insects, however must be collected properly and its accuracy depends on this on suitable conditions for insects.

The **P**ost-**M**ortem **I**nterval (**PMI**) determination has been the most frequently attempted forensic investigation. The Forensic Pathologist, Medical Examiner, or the Coroner has been handling the work. However, it is the Forensic Entomologist, now, who provides the information on the post-mortem interval. It is determined from:

- The life cycle of the specific insects, and
- The faunal succession schedule of different species of insects

There are many variables like temperature, humidity and habitat. There are also unknown factors like the lifestyle of the subject, arrival time of the insects. The time of death determination, therefore, is often an intelligent guess.

> *In a small town of Italy the decomposing body of a woman was discovered in a tightly closed room, in the month of September. Nobody had been living in that house for a long time. The body was lying face down near the door and there were bloodstains on the floor and on the walls. The injury on the head was from a radiator hooker. It seems the woman had dragged herself to the door where she was found.*
>
> *The investigators called in Forensic Entomologists to the scene. The team found that the temperature and humidity of the room had been more or less constant throughout the past relevant period. There were a large number of maggots, pupae and puparia. Fly larvae of all stages (I instars, II instars, III instars) were found on the putrefying body. They were collected and preserved. Some of the pupae developed into flies which, in turn, were used to study their breeding.*
>
> *The findings were:*
>
> 1. *Only one type of insect (mono-specific necrophagous fly) had attacked the corpse.*
> 2. *No vertebrates like mice had nibbled the body.*
> 3. *Absence of other insects (necrophagous biodiversity) and absence of faunal succession schedule hindered estimate of the time of death.*
> 4. *The best estimate of the PMI, from the detailed study of the life cycle of the fly, that could be given, was that the death had taken place at least four months earlier*[5].

36.4.2 Culprit-Weapon-Victim Linkage

Dogs have been extensively used to locate narcotics, liquor, explosives and even the culprit in criminal investigations. But to harness flies to hunt the criminal is (or was) a fantastic idea.

5. For details: *Aggarwal's Internet Journal of Forensic Medicine and Toxicology*, 5 (1) 2004.

Ordinarily, the linkage of the culprit, victim and/or of the weapon *inter se* via Forensic Entomology is not possible as the culprit and the weapon are not at the scene when the insects generate the entomological evidence. However, it may happen in some odd cases. The Chinese case (*supra*) is, incidentally, the first recorded case and the oldest case — of thirteenth century — where Forensic Entomology was used to identify the culprit. Is it also the last such case? The author has not come across another similar one!

36.4.3 Kidnapper's Identification

It is comparatively a case of kidnapping, sexual abuse, pornography and murder, Danielle Van Dam, a girl child of 7 years, went missing on 1 February, 2002. The parents and police searched for her but to no avail. Then on 27 February, 2002 the naked putrefied body of the girl was found on the road side, quite close to the residence of her parents.

A neighbour of the deceased's family, Westerfield, was suspected to be the murderer as he had been at home on the crucial day. He was also seen to leave clothes with a launderer. The clothes were later found to carry the victim's blood. Further, the police recovered fingerprints, fibres and hair from the residence and vehicle of the suspect which were similar to those of the victim. Pictures of child pornography were also found in his computer. He was booked for murder.

The forensic evidence relating to blood, hair, fibre. played their respective roles. But Forensic Entomology provided the decisive blow.

Both sides produced about half a dozen Forensic Entomologists. The main question was to find the post-mortem interval (PMI). The whole evidence was thrashed threadbare. The court accepted the prosecution's version of the time of death and found the accused guilty of kidnapping and of first degree murder.(CH)

36.4.4 Child Abuse

Child abuse, followed by murder, is a fairly frequent crime in India. Usually, a child of tender age is enticed, taken to a lonely place abused and murdered. The body is thrown at a secluded place or buried. The body may be discovered after days or sometimes even after weeks.

The body so discovered is often decomposed and infested by insects to varying extent, depending upon the post-mortem interval, temperature, humidity, environment. The presence of eggs, maggots, larvae of various stages of development, pupae and puparia (the life cycle of a necrophagous fly) and the faunal succession can indicate the PMI. A lot of work is being done to find the correct PMI. Yet the success rate for ascertaining the correct PMI eludes the scientists at present. The plethora of variables obstruct the investigations.

In a case of child abuse and murder, entomological evidence was collected from different parts of the body. It was found that the child was killed 6-8 days before the post-mortem. The examination of the entomological evidence collected from the facial orifices indicated that the death had taken place 8-9 days prior to the collection of the insect population. When the evidence from the ano-genital parts was examined, the insects' life cycle indicated that the death had taken place about 14 days earlier. Apparently, the child was alive for 14 days but the ano-genital parts of the abused child had not been cleaned for that period and the faunal evidence developed even when the child was still alive. (CH)

36.4.5 Narcotics' Origin

The menace of drug abuse is a worldwide scourge. If the narcotic is of plant origin its place or country of cultivation can be found. One of the most important narcotics, volume-wise and cases-wise, is cannabis. The drug is often in the form of dried leaves and stems, compressed to reduce the volume. Cannabis in this form carries faunal evidence, dead or alive. As the fauna is region and climate specific, the place from where the drug has come can be identified. It will certainly be useful to fix the place of origin of the drug. The processing of the entomological evidence is more convenient than the chemical methods utilized at present to find the place of origin of the drug.

Raw opium is also amenable to find the place of origin via entomological evidence. Highly processed drugs like heroin, cocaine crystals and synthetic drugs remain outside the domain of Forensic Entomology.

Insect evidence **may reveal the presence of drugs**. Maggots bio-accumulate them enabling analysis to determine the type of drug present.

36.4.6 Punishment Stings

It is quite unfortunate that some people punish their wards and household servants by subjecting them to stings by wasp and bees. Not only the stings are painful, they may scar the victims psychologically, sometimes making them mental wrecks. If a number of wasps or bees sting the victim, he or she may die. In such cases Forensic Entomology may provide evidence in some such cases against the culprit.

36.4.7 Illegal Poaching

Forensic entomology has also been utilized in illegal poaching.

> *Some years ago two baby black bears were found shot dead in Canada with their gall bladders removed, presumably to be used as medicine.*
>
> *Witnesses had heard gunshots and spotted a vehicle. Two men were found hiding near the bear's bodies and witnesses were able to confirm the suspects belonged to the vehicle that had been sighted earlier.*
>
> *The witnesses' recollections were helpful leads, but the police officers could not hold the two men solely on suspicion. More evidence was needed in order to connect the two suspects to the crime. Blowfly eggs were found and collected from the bears' bodies and sent to an experienced entomologist. Anderson, as, knew that blowfly eggs take twenty-two hours to hatch in the hot summer temperatures in which the bears were found. By counting back twenty-two hours and taking into account the weather data for the time the bears were discovered, the expert was able to find when the fly eggs were first deposited on the bodies. The time found for the eggs matched with the time the witnesses spotted the two suspects near the crime scene, heard the gun shots and saw their vehicle.* (CH)

36.4.8 The shifting of the body

The culprit may shift the body to fake the scene or to a hiding place. Insects on the body may be native to the first habitat and not to the second. This will show that not only was the body moved, but it will also indicate the real crime scene.

36.4.9 Body disturbed after death

Disturbing the body may disturb the insects cycle, and the entomologist may be able to determine not only the date of death, but also the date when the body was disturbed.

36.4.10 Presence/position of wounds

The decomposition often obscures wounds. Their presence and position are indicated by the insect colonies. They colonise in a specific pattern, usually laying eggs first in the facial orifices, unless there are wounds, where they colonise first. Then proceed down the body. If the maggot activity is centred away from the natural orifices, then it is likely that this is the site of a wound.

36.4.11 Suspect at the crime scene

An insect from the scene on the person of the accused places him at the scene.

36.4.12 Child or senior abuse/neglect

Some insects will colonise wounds or unclean areas on a living person. This is called cutaneous myiasis.

In these cases, the victim is still alive, but maggot infested. A forensic entomologist will be able to tell when the wound or abuse occurred. For instance, in the case of neglected children,

the onset of maggot infestation will give a minimum time interval since the child last had a diaper change. Such cases occur particularly among young children and seniors.

36.4.13 Miscellaneous

The use of Forensic Entomology in diverse criminal situations is increasing steadily. The following are some of the additional avenues where entomology can help:

- Identification of Scene of Occurrence.
- Time of Decapitation.
- Time of Dismemberment.
- Shifting of the *corpus delicti*.
- Bite marks of ants and cockroaches.
- Blood flyspecks. Flyspecks are sometimes confused with bloodstains. Are they the result of the criminal act or are the flyspecks left by the insects?
- The insect's body material may contain blood or other body material from the victim, which can be used to find the DNA profile of the victim. It is rare when residue from the insects is available.
- The insect's body material may be available. It may contain the poison (or narcotic drug) which might have caused the death of the victim. Identification of poison from the insect's body material has been given the fancy name: **Entomotoxicology**. However, if the body of the victim is available, it provides better material for locating the drug. It may not be available in some cases.
- Neglect of wounds on the incapacitated (old) person under both private and institutional care. The presence of fauna will indicate neglect.
- The role of the insects (bees and wasps) in causing car accidents when there is only a single driver occupant in the vehicle.

36.5 EVIDENTIARY CLUES

The evidentiary clues in Forensic Entomology are insects, their excretion and their remnants. They have to be located, collected, preserved, packed, transported, stored and evaluated. The various steps have to be taken in such a way their identity, relevancy, integrity, authenticity *vis-a-vis* the incident being investigated, continuity of the chain of custody is preserved and that legal formalities are observed in letter and spirit so that the courts do not question their validity and legitimacy on those counts and reject the evidence.

Forensic Entomology is a comparatively new branch. The police investigator may not be well versed in handling the evidence. It is, therefore, advisable, rather essential, to associate a well-versed Forensic Entomologist not only at the crime scene but also at the time of post-mortem examination also.

36.5.1 Location

The sources for faunal evidentiary clue materials are mainly:

1. **The Corpse**: The usual sites for the insects in the exposed or rotting body. Eggs and maggots are found in the natural orifices, wounds and injuries created by predatory creatures.
2. **The moist and loose soil:** under the corpse. The entities may have fallen there. Beetles also hide themselves in the soil on which the dead body lies.

3. **Clothes on Corpse**: The entomological creatures and material may move into the dead body clothes.
4. **The Coffin and the Burial Site:** The evidence may also be found in the coffin or burial site.
5. **Corpse Coverings (Bags, Sheets)**: The coverings of the corpse or its parts carry faunal evidence when they are used to keep (and carry) the corpse in an advance stage of decomposition or the body is kept in them for a long time.
6. **Burrows:** Insect may also be found in burrows which the insects may have created in the earth under the corpse, if the body had been lying there for a considerable time.
7. **The site (Scene)**

36.5.2 Documentation of Recovery

The discovery/recovery of the faunal evidence (like other evidence) is properly documented with the usual modes the location of the evidence must be documented by the usual modes:

1. **A video film:** of the scene and the surroundings along with close up shots of the evidential clue
2. **Photography:** the scene, the evidence is photographed; with identity chit, which contains the FIR No., Police station, date and the name of the investigator along with a scale. Both close-ups (to specify the evidence) and general photographs (to fix the site) are taken, usually in daylight. A flash light gives poor results.
3. **Sketch to scale:** 3-dimensional sketching software has come up, it should be used.
4. **Textual notes:** record of the scene and the conditions of the evidence are indispensable.
5. **Record the ecological environmental condition:** for proper appreciation of the faunal evidence:
   - The climate of the scene area prior and subsequent to the initiation of the examination of the scene. Usually, about 5 days' climate prior to and before the occurrence should be noted. The information helps to estimate the life cycle of the predatory insects on the corpse.
   - The availability of air and nature of soil underneath the body should be noted. They play an important role in the developments of insects and their products.

36.5.3 Arthropod Evidence Collection Principles

The officer collecting the clues should:

1. Document the evidence at the scene, on the body of the victim, including insects bite marks.
2. Collect one spoon full of insects each from at least three different sites of the corpse and the crime scene in three different, clearly labelled jars.
3. Put half of the insects in 98% ethanol/methylated spirit. Killed insects can be stored in frozen condition. Other media (formalin) are not used.
4. Kill the arthropods with hot water before placing them in ethanol.
5. Place half of the insects alive in a refrigerator. Cover them with fabric.
6. Keep white larvae separate from brownish larvae.
7. Keep larvae and adults separately.

8. Secure the help of Forensic Entomologist for handling the evidence, whenever possible.
9. Write complete information (location, exact time, date, initials) on a properly secured/attached label.
10. Only an experienced entomologist knowing the local entomological fauna[6] handles the evidence.

36.5.4 Collection process

Forensic investigations are based upon on clue materials collected from the victim, from the culprit and from the crime scene, which are located, seized, recorded, preserved packed and seized as per law of the land and departmental rules The total process vis-à-vis insect evidence is a hard nut to crack, in view of the variables (*supra*), discussed above. It is not a job of investigating officer alone, he should involve a forensic entomologist who understands the surroundings also.

36.5.4.1 Collection from the scene

If the scene is an outdoor scene, the Forensic Entomologist notes/collects:

1. the landscape, plants and soil types
2. The weather
3. The Temperature; it is especially important and if possible, a portable recording device is left to record long-term changes.
4. A soil sample.

If the scene is indoors, an investigator looks for access points where insects could get in. From the body, the forensic entomologist takes several samples from different areas of the body.

1. If there are maggots, some are collected, placed in boiling water and preserved in alcohol. This stops development. Other maggots are collected alive so that they can be kept until they reach adulthood. At this stage, the species can be determined.
2. Normally, eggs are collected only if there are no later stages associated with the body. Again, some are taken and preserved in alcohol while others are watched until they hatch.
3. Empty pupal casings (puperia moult) are also collected.
4. Adult flies are collected if the wings are crumpled. This suggests they have emerged from its moult and can be linked to the body. Otherwise, they are not collected since they may have just arrived to the scene from outside.

The careful and accurate collection of insect evidence at the scene is essential. Ideally, an entomologist collects a range of insects of different stages from different areas of the body and the surroundings (e.g., clothing or soil). Different species, or insects collected from different areas, are kept separately.

36.5.4.2 Evidence from flies

The entomological evidence from the flies are eggs, larvae or maggots, pupae, empty pupal cases (moult) or as adults.

36.5.4.2.1 Eggs

Eggs are laid in clumps. They are usually found in wounds or natural orifices. They are collected with a damp paint brush. Half are preserved in alcohol and half are collected alive.

6. In some area the entomologist have prepared a faunal dictionary of the local fauna, It is useful.

Eggs are especially important when maggots or later insect stage products are absent. The time of hatching is vital and their progress is monitored every few hours.

36.5.4.2.2 Maggots

Maggots are found on or near the remains and may be in large numbers. The masses generate heat, which speeds up development. The site of the maggot mass, the temperature (and size) of each mass are important. Large maggots are usually older, but small maggots may belong to a different species. So maggots of different sizes are collected separately. Half the sample is kept alive and half preserved immediately.

Preservation allows the entomologist to see what stage the maggots were in when collected. Preserved specimens may also be used as evidence in court.

36.5.4.2.3 Pupae

Pupae are dark brown, oval, and the size range from 2-20 mm. They and their moulting (carcasses) are very important but they are easily missed. Pupae live away from the wet food source. They won't grow and their exact age cannot be determined until the adult emerges. They are found:

- In clothing
- Under rugs

Empty pupal carcass looks like pupae but has one end open from where the adult fly had emerged. They do not provide substantial evidence. Pupae are not preserved.

36.5.4.2.4 Adult Blow Flies

Adult Blow Flies are not as important as eggs, maggots or pupae. They indicate only the species of insect.

Flies, smaller than blow flies, are important at all stages as they indicate the succession of insects on the remains

36.5.4.2.5 Beetles

Beetles (Coleoptera) are found as adults, larvae, pupae and as cast skins.

All beetle stages are important. They move fast and are often found under the body, or in and under clothing. They are collected and preserved in alcohol.

36.5.5 Collection Kit

Proper collection of faunal evidence needs some elementary collection tools. A brief list is given below:

1. Camera and video camera, to fix the evidence site:
2. Net to catch flies. Sticky traps are also used instead.
3. Live specimen containers; killed creatures container jar; forceps; spoon; small paint-brushes;
4. Sifting screens
5. Preservatives: usually 98% alcohol (ethanol) is used.
6. Thermometers to measure body temperature and/or temperature of the surroundings.

7. Recording materials like labels, pencil, ruler, crime scene form, if any, prescribed by the authorities.
8. Gloves, hand towels and hand wash are usually taken along to maintain hygiene.

36.6 EVALUATION

The evaluation of the faunal evidence is highly specialised work. A Forensic Entomologist needs long experience, thorough knowledge of not only entomology but also the local environment and its arthropod faunal population, their habitat preferences and breeding modes and schedules.

36.6.1 Sources of Errors

There are many sources of error in the evaluation of faunal evidence. The entomologist has to vigilant about them. Otherwise, the result can lead to injustice. The following aspects are kept in mind:

1. The influence of environment is important. It can stunt or enhance the rate of growth of the creatures
2. Flies will also feed on the blood and then pass the partially digested blood in its faeces, which are known as "flyspecks". Flies will also regurgitate and possibly drop a blood droplet on a remote surface, which may serve to confuse bloodstain analysis.
3. There are predatory insects, which eat eggs and larvae laid by the earlier insects. Thus, they can mislead the entomologist in the evaluation of PMI.

The main entomological evaluation is the identification and differentiation of the species of the insect, its remains and remnants. Modern technology has facilitated the process and made it easy. The seasoned entomologists use the following tools and techniques routinely.

36.6.2 Traditional Tools

Traditional tools for the examination Forensic Entomological evidence are still the first tool used in the evaluation of the evidence. The important instruments are:

1. **Hand Magnifier:** it is now fitted with lighting arrangement.
2. **Microscopes**: stereo and research microscopes with supporting paraphernalia are common.
3. **Spot light lamps**
4. **Staining agents/other chemicals**: for example, Potassium permanganate staining is used to study eggs. They are examined after rinsing with saline in 1% potassium permanganate solution for about one minute and then studied under a microscope with a calibrated eyepiece, to evaluate and compare (with standards) its morphological characteristics like the size (length and width).

36.6.3 Modern Tools

36.6.3.1 Scanning Electron Microscope

Among the modern tools, the Scanning Electron Microscope (SEM) is assuming great importance. Its high magnifying power, high resolution and three dimensional images are making it the tool of choice for morphological studies of the entomological evidence like fly eggs and larvae, which help to determine the PMI. The SEM reveals the fine distinction between the eggs and larvae of various species through clear images of the shape, size and individual morphological characteristics of the entities.

The SEM is becoming an indispensable tool for correct and proper evaluations.

36.6.3.2 DNA Profiling

DNA is being used to identify the species of the insects when the morphological studies do not provide adequate data to differentiate the species.

36.6.3.3 Gene studies

The usual methods to find the age of the flies was through the morphological characters and size of the instars. Studies have shown some promising results for the determination of the age of an egg or a pupa, based on changes of some genes. These genes are likely to have varied levels during different times of the egg or pupa development process and change linearly with the age of the egg or pupa.

The chart of changes prepared in the case in hand is compared with a standard chart prepared from the same known species and the age of the evidence ascertained with a high confidence value.

The technique is likely to gain popularity and would provide more accurate PMI in the coming times.

With the continued developments of newer and better techniques and the arthropods being so plentiful and widespread, they are bound to play an important role in the dissemination of justice in the coming times.

36.7 CONCLUSION

Forensic Entomology has a poor past, unimpressive present and a bleak future.

Firstly, it is involved in most of the heinous crimes like murders, rape-murders, spouse killing and infanticide. The courts demand proof beyond doubt. Forensic Entomology seldom goes beyond corroboration. It can unravel the time of death, almost correctly if the environmental and upkeep of the corpse is known. But it seldom happens.

Secondly, there have been tremendous research inputs in tools and techniques. They have increased the confidence level of the findings impressively. SEM for morphological studies, DNA for genetic identification of the species, HPLC and Mass Spectroscopy for poisonous residues in the body. have changed the entire scenario in the field but they play a limited role in Forensic Entomology evaluations.

Lastly, the need of the speciality is expanding. It is no longer the fiefdom of the Forensic pathology. It plays substantial role in the fields of hygiene, food processing and preservation system and in environmental pollution control. They hold a beckoning light for the speciality. However, some stumbling blocks hider its full exploitation:

1. Inadequate research.
2. Ignorance about the speciality.
3. Limited avenues; even in USA there are only 8 certified Forensic Entomologists!
4. Limited number of Forensic Entomology institutes.

37.1 TESTIMONIAL COMPULSION[1]

Author's Summary

This judgment clarified the intent and content of the Article 20(3); which says that an accused person cannot be compelled to be a witness against himself. whether collection of certain types of evidence, (handwriting/fingerprints/footprints photograph, etc.) from a suspect, contravenes the constitution or not. Many a court said it does; others said it did not. Thus a confusion was created.

The full bench in this case decided it does not. They ruled collection of the clues in not evidence. It becomes evidence after the expert evaluates it; which may favour the accused also. They also mentioned that the Constitution makers did not intend to obstruct justice.

This judgment thus made it possible to use important forensic clues in the delivery of justice.

Highlights italicised

1. *State of Bombay v Kathi Kalu Oghad,* AIR 1961 SC 1808 : (1962) 3 SCR 10 : (1961) 2 Cr LJ 856 (SC).

Relevant Extract Verbatim

It is not necessary to state in any detail the facts of each of the cases now before us. We shall, therefore, state only so much of the facts as have occasioned calling in aid of the provisions of clause (3) of Article 20 of the Constitution. In the first case, namely, Criminal Appeal 146 of 1958, the State of Bombay is the appellant. The respondent was charged, along with another person, under section 302, read with section 34 of the Indian Penal Code, as also under section 19(e) of the Indian Arms Act (XI of 1878). The trial court found him guilty of those charges and sentenced him to imprisonment for life under section 302 read with section 34 of the Indian Penal Code and to a term of two years rigorous imprisonment for the offence under the Arms Act. At the trial, the identification of the respondent, as one of the two alleged culprits, was the most important question to be decided by the court. Besides other evidence, the prosecution adduced in evidence a chit-Ex. 5 alleged to be in his handwriting and said to have been given by him. In order to prove that Ex. 5 was in the handwriting of the respondent, the police had obtained from him, during the investigation, three specimen handwritings of his on three separate sheets of paper which were marked as Exs. 27, 28 and 29. The disputed document, namely, Ex. 5 was compared with the admitted handwriting on Exs. 27, 28 and 29 by the handwriting expert whose evidence was to the effect that they are all writing by the same person. At the trial and in the High Court, the question was raised as to the admissibility of the specimen writings contained in Exs. 27, 28 and 29, in view of the provisions of Article 20(3) of the Constitution. It is an admitted fact that those specimen writings of the accused had been taken by the police while he was in police custody, but it was disputed whether the accused had been compelled to give those writings within the meaning of clause (3) of Article 20. The plea of the accused that he was forced by the Deputy Superintendent of Police to give those writings has not been accepted by the learned trial judge. But those documents have been excluded from consideration as inadmissible evidence, on the ground that though there was no threat or force used by the police in obtaining those writings from the accused person, yet in the view of the court "the element of compulsion was implicit in his being at that time in police custody". In this conclusion both the trial judge and High Court have agreed. The identification of the accused person was also sought to be proved by the evidence of witnesses, who identified him at an identification parade. But the holding of the identification parade has not been sought to be brought within the prohibition of clause (3) of Article 20. After eliminating the Exs. 27, 28 and 29 from their consideration, the High Court, on a consideration of the other evidence in the case came to the conclusion that the identity of the respondent had not been established beyond a reasonable doubt. Hence, giving him the benefit of doubt, they acquitted him. The State of Bombay moved this court and obtained special leave to appeal from the judgment and order of acquittal, passed by the High Court. On these facts, the only questions of constitutional importance that this Bench has to determine are: (1) whether by the production of the specimen handwritings – Exs. 27, 28 and 29 – the accused could be said to have been 'a witness against himself within the meaning of Article 20(3) of the Constitution; and (2) whether the mere fact that when those specimen handwritings had been given, the accused person was in police custody could, by itself, amount to compulsion, apart from any other circumstances which could be urged as vitiating the consent of the accused in giving those specimen handwritings. This Bench is not concerned with the further question whether in all the circumstances disclosed by the evidence in this case, the accused could be said to have compelled, as a matter of fact, to give those specimens.

The arguments at the Bar may be classified as taking three distinct lines.

> *The first line, on the one extreme, may be said to have been taken by Mr. Sikri, the Advocate General of Punjab, and which may be characterised as a narrow view, runs as follows: Clause (3) aforesaid, in view of its setting, its history and the policy underlying, the privilege accorded by the Constitution to an accused person, should not be applied at the stage of investigation of*

an offence. It should be confined to cases of compulsory extraction of incriminating statements or communications by an accused person in court, the expression 'compelled to be a witness' being understood as meaning 'being compelled to give oral testimony'. It does not include the compulsory production of documents. Similarly, it does not prohibit the compulsory exhibition or examination of the body of the accused, or any part of it, or the taking of specimen writing, thumb impression, impression of the palm or the feet or the fingers of an accused. Whether or not there has been compulsion should be judged by the nature of the action taken by the authority, or the court that determines the controversy, and not the state of mind of the accused.

On the other extreme is the argument by Mr. S.P. Verma, for the accused in the first case, who contended that the clause aforesaid of the Constitution gives complete protection of the widest amplitude to an accused person, irrespective of the time and place and of the nature of the evidence, whether it is oral or documentary or material. The extreme form, which his argument took can best be stated in his own words as follows:—

> *Anything caused, by any kind of threat or inducement, to be said or done by a person, accused or likely to be accused of any offence, by non-voluntary positive act or speech of that person, which furthers the cause of any prosecution against him or which results or is likely to result in the incrimination of that person qua any offence, is violative of the fundamental right guaranteed under clause (3), Article 20 of the Constitution of India.*

According to his argument, if an accused person makes any statement or any discovery, there is not only a rebuttable presumption that he had been compelled to do so, but that it should be taken as a conclusive proof of the inferential fact. Any kind of inducement, according to him, is also included in the expression 'compulsion' by the police or someone else. The test, according to him, is not the volition of the accused but the incriminatory nature of the statement or communication. Hence, any statement made to a police officer, while in police custody, brings the same within the prohibitory ambit of the clause of the Constitution. On the face of them, the propositions propounded by Mr. Verma are much too broadly and widely stated to be accepted.

The third view, which may be characterised as an intermediate view, was advocated by the learned Attorney-General, appearing for the Union. *According to him, a person seeking protection under the clause must satisfy all the four constituent elements contained in clause (3) of article 20 namely:—(1) he must be an accused person; (2) he must have been compelled; (3) the compulsion must be to be a witness; and (4) against himself. Compulsion, according to him, means coercion or constraint and does not include mere asking by the police to do a certain thing or the direction by a court to give a thumb impression or specimen of writing. In other words, compulsion has to be equated to what has been sometimes characterised as 'third degree' methods to exhort confessional statements. "To be a witness" is an expression which must be understood in consonance with the existing law of evidence and criminal procedure, e.g.*, sections 27 and 73 of the Evidence Act and section 94 and 96 of the Code of Criminal Procedure. Though, according to English law, the expression is confined to oral testimony he was prepared to go to the length of conceding that any statement, whether oral or in writing by an accused person, transmitting his knowledge disclosing relevant facts of which he was aware, would amount to 'being a witness' against himself. But mere production of some material evidence, by itself, would not come within the ambit of the expression "to be witness".

The several questions for decision arising out of this batch of cases have to be answered with reference to the provisions of clause (3) of Article 20 of the Constitution which is in these terms:

No person accused of any offence shall be compelled to be a witness against himself.

These provisions came up for consideration by the full court in the case of *M.P. Sharma v Satish Chandra.*[1] Though the question directly arising for decision, in that case, was whether a search and seizure of documents under the provisions of sections 94 and 96 of the Code of Criminal Procedure came within the ambit of the prohibition of clause (3) of Article 20 of

the Constitution, this court covered a much wider field. Besides laying down that the search and seizure complained of in that case were not within the prohibition, this court examined the origin and scope of the doctrine of protection against self-incrimination with reference to English Law and the Constitution of the United States of America, with particular reference to the Fourth and Fifth Amendments. On an examination of the case law in England and America and the standard textbooks on evidence, like Phipson and Wigmore, and other authorities, this court observed as follows:—

> *Broadly stated the guarantee in Article 20(3) is against "testimonial compulsion". It is suggested that this is confined to the oral evidence of a person standing his trial for an offence when called to the witness stand. We can see no reason to confine the content of the constitutional guarantee to this barely literal import. So to limit it would be to rob the guarantee of its substantial purpose and to miss the substance for the sound as stated in certain American decisions. The phrase used in article 20(3) is "to be a witness". A person can "be a witness" not merely by giving oral evidence but also by producing documents or making intelligible gestures as in the case of a dumb witness (see section 119 of the Evidence Act) or the like "To be a witness" is nothing more than "to furnish evidence", and such evidence can be furnished through the lips or by production of a thing or of a document or in other modes. So far as production of documents is concerned, no doubt section 139 of the Evidence Act says that a person producing a document on summons is not a witness. But that section is meant to regulate the right of cross-examination. It is not a guide to the connotation of the word "witness", which must be understood in its natural sense, i.e., as referring to a person who furnishes evidence. Indeed, every positive volitional act which furnishes evidence is testimony, and testimonial compulsion connotes coercion which procures the positive volitional evidentiary acts of the person, as opposed to the negative attitude of silence or submission on his part. Nor is there any reason to think that the protection in respect of the evidence so procured is confined to what transpires at the trial in the court room. The phrase used in article 20(3) is "to be a witness" and not to "appear as a witness". It follows that the protection afforded to an accused insofar as it is related to the phrase "to be a witness" is not merely in respect of testimonial compulsion in the court room but may well extend to compelled testimony previously obtained from him. It is available, therefore, to a person against whom a formal accusation relating to the commission of an offence has been levelled which in the normal course may result in prosecution. Whether it is available to other persons in other situations does not call for decision in this case.*

This court did not accept the contention that the guarantee against testimonial compulsion is to be confined to oral testimony at the witness stand when standing trial for an offence. The guarantee was, thus, held to include not only oral testimony given in court but also to statements in writing which incriminated the maker when figuring as an accused person. After having heard elaborate arguments for and against the views thus expressed by this court after full deliberation, we do not find any good reasons for departing from those views. But the court went on to observe that "to be a witness" means "to furnish evidence" and includes not only oral testimony or statements in writing of the accused but also the production of thing or of evidence by other modes. It may be that this court did not intend to lay down, certainly it was not under discussion of the court as a point directly arising for decision, that calling upon a person accused of an offence to give his thumb impression, his impression of palm or fingers or of sample handwriting or signature comes within the ambit of "to be a witness", which has been equated to furnish evidence". Whether or not this court intended to lay down the rule of law in those wide term has been the subject-matter of decisions in the different High Courts in this country. Those decisions are, by no means, uniform; and conflicting views have been expressed even in the same High Court on different occasions. It will serve no useful purpose to examine those decisions in detail. It is enough to point out that the most recent decision, to which our attention was called, is of a Full Bench of the Kerala High Court in the case of *State of Kerala v K.K. Sankaran Nair*[2]. In that case, Ansari, C.J., who delivered the opinion of the court, has made reference to and examined in detail the pronouncements of the different

2. AIR1960 Ker 392.

High Courts. Ultimately he came to the conclusion that the decision of this court in the case of *M.P. Sharma v Satish Chandra*,[3] also covered the case of a specimen handwriting given by an accused person, under compulsion.

> *"To be a witness" may be equivalent to "furnishing evidence" in the sense of making oral or written statements, but not in the larger sense of the expression so as to include giving of thumb impression or impression of palm or foot or fingers or specimen writing or exposing a part of the body by an accused person for purpose of identification. "Furnishing evidence" in the latter sense could not have been within the contemplation of the Constitution makers for the simple reason that – though they may have intended to protect an accused person from the hazards of self-incrimination, in the light of the English law on the subject – they could not have intended to put obstacles in the way of efficient and effective investigation into crime and of bringing criminals to justice. The taking of impressions of parts of the body of an accused person very often becomes necessary to help the investigation of a crime. It is as much necessary to protect an accused person against being compelled to incriminate himself, as to arm the agents of law and the law courts with legitimate powers to bring offenders to justice. Furthermore it must be assumed that the Constitution makers were aware of the existing law; for example section 73 of the Evidence Act or sections 5 and 6 of the Identification of Prisoners Act (XXXIII of 1910). Section 5 authorises a magistrate to direct any person to allow his measurements or photographs to be taken, if he is satisfied that it is expedient for the purposes of any investigation or proceeding under the Code of Criminal Procedure to do so: 'Measurements' include finger impressions and footprint impressions. If any such person who is directed by a magistrate, under section 5 of the Act to allow his measurements or photographs to be taken resists or refuses to allow the taking of the measurements or photographs, it has been declared lawful by section 6 to use all necessary means to secure the taking of the required measurements or photographs. Similarly section 73 of the Evidence Act authorises the court to permit the taking of finger impression or a specimen handwriting or signature of a person present in court, if necessary for the purpose of comparison.*

The matter may be looked at from another point of view. The giving of finger impression or of specimen signature or of handwriting, strictly speaking, is not 'to be a witness'. 'To be a witness' means imparting knowledge in respect of relevant facts by means of oral statements or statements in writing by a person who has personal knowledge of the facts to be communicated to a court or to a person holding an enquiry or investigation. A person is said 'to be a witness' to a certain state of facts which has to be determined by a court or authority authorised to come to a decision by testifying to what he has seen, or something he has heard which is capable of being heard and is not hit by the rule excluding hearsay, or giving his opinion, as an expert, in respect of matters in controversy. Evidence has been classified by text writers into three categories, namely, (1) oral testimony; (2) evidence furnished by documents; and (3) material evidence. We have already indicated that we are in agreement with the full court decision in *Sharma's* case[4] that the prohibition in clause (3) of Article 20 covers not only oral testimony given by a person accused of an offence but also his written statements which may have a bearing on the controversy with reference to the charge against him. The accused may have documentary evidence in his possession which may throw some light on the controversy. If it is a document which is not his statement conveying his personal knowledge relating to the charge against him, he may be called upon by the court to produce that document in accordance with the provisions of section 139 of the Evidence Act, which, in turn provides that a person may be summoned to produce a document in his possession or power and that he does not become a witness by the mere fact that he has produced it, and therefore, he can be cross-examined if he is called as a witness who has made statements conveying his personal knowledge by reference to the contents of the document or if he has given his statements in court otherwise than by reference to the contents of the documents. In our opinion, therefore, the observation of this court in *Sharma's* case[1] that

3. AIR 1954 SC 300.
4. *Ibid.*

section 139 of the Evidence Act has no bearing on the connotation of the word 'witness' is not entirely well-founded in law. It is well-established that clause (3) of article 20 directed against self-incrimination by an accused person. Self-incrimination must mean conveying information based upon the personal knowledge of the person giving the information and cannot include merely the mechanical process of producing documents in court which may throw a light on any of the points in controversy, but which do not contain any statements of the accused based on his personal knowledge. For example, the accused person may be in possession of a document which is in his writing or which contains his signature or his thumb impression. The production of such a document, with a view to comparison of the writing or the signature or the impression, is not the statement of an accused person, which can be said to be of the nature of personal testimony. When an accused person is called upon by the court or any other authority holding an investigation to give his finger impression or signature or a specimen of his handwriting, he is not giving any testimony of the nature of a 'personal testimony.' The giving of a 'personal testimony' must depend upon his volition. He can make any kind of statement or may refuse to make any statement. But his finger impressions or his handwriting in spite of efforts at concealing the true nature of it by dissimulation cannot change their intrinsic character. Thus, the giving of finger impressions or of specimen writing or of signatures by an accused person, though it may amount to furnishing evidence in the large sense, is not included within the expression 'to be a witness.'

> ***In order that a testimony by an accused person may be said to have been self-incriminatory, the compulsion of which comes within the prohibition of the constitutional provision, it must be of such a character that by itself it should have the tendency of incriminating the accused, if not also of actually doing so. In other words, it should be a statement which makes the case against the accused person at least probable, considered by itself. A specimen handwriting or signature or finger impressions by themselves are no testimony at all, being wholly innocuous because they are unchangeable except in rare cases where the ridges of the fingers or the style of writing have been tampered with. They are only materials for comparison in order to lend assurance to the court that its inference based on other pieces of evidence is reliable. They are neither oral nor documentary evidence but belong to the third category of material evidence which is outside the limit of 'testimony'.***

Similarly, during the investigation of a crime by the police, if an accused person were to point out the place where the *corpus delicti* was lying concealed and in pursuance of such an information being given by an accused person, discovery is made within the meaning of section 27 of the Evidence Act, such information and the discovery made as a result of the information may be proved in evidence even though it may tend to incriminate the person giving the information, while in police custody. Unless it is held that the provisions of section 27 of the Evidence Act, insofar as they make it admissible evidence which has the tendency to incriminate the giver of the information, are unconstitutional as coming within the prohibition of clause (3) of Article 20, such information would amount to furnishing evidence. This court in *Sharma's* case[5] was not concerned with pronouncing upon the constitutionality of the provisions of section 27 of the Evidence Act. It could not, therefore, be said to have laid it down that such evidence could not be adduced by the prosecution at the trial of the giver of the information for an alleged crime. The question whether section 27 of the Evidence Act was constitutional because it offended article 14 of the Constitution was considered by this court in the case of *State of Uttar Pradesh v Deomen Upadhyaya.*[6] It was held by this court that section 27 of the Evidence Act did not offend Article 14 of the Constitution and was, therefore, *intra vires.* But the question whether it was unconstitutional because it contravened the provisions of clause (3) of Article 20 was not

5. *Ibid.*
6. AIR 1945 SC 300.

considered in that case. That question may, therefore, be treated as an open one. The question has been raised in one of the cases before us and has, therefore, to be decided. The information was given by an accused person to a police officer leading to the discovery of a fact which may or may not prove incriminatory has been made admissible in evidence by that section. If it is not incriminatory of the person giving the information, the question does not arise. It can arise only when it is of an incriminatory character so far as the giver of the information is concerned. If the self-incriminatory information has been given by an accused person without any threat, that will be admissible in evidence and that will not be hit by the provisions of clause (3) of Article 20 of the Constitution for the reason that there has been no compulsion. It must, therefore, be held that the provisions of section 27 of the Evidence Act are not within the prohibition aforesaid, unless compulsion had been used in obtaining the information.

In this connection the question was raised before us that in order to bring the case within the prohibition of clause (3) of Article 20, it is not necessary that the statement should have been made by the accused person at a time when he fulfilled that character; it is enough that he should have been an accused person at the time when the statement was sought to be proved in court, even though he may not have been an accused person at the time he had made that statement. The correctness of the decision of the Constitution Bench of this court in the case of *Mohammed Dastagir v State of Madras,* was questioned because it was said that it ran counter to the observations of the full court in *Sharma's* case. In the full court decision of this court this question did not directly arise nor was it decided. On the other hand, in this court, *Sharma's* case,[7] held that the protection under Article 20(3) of the Constitution is available to a person against whom a formal accusation had been levelled, inasmuch as a first information report had been lodged against him. *Sharma's* case, therefore, did not decide anything to the contrary of what this Court said in *Mohammed Dastagir v State of Madras*[8] The latter decision in our opinion lays down the law correctly.

In order to bring the evidence within the inhibitions of clause (3) of Article 20, it must be shown not only that the person making the statement was an accused at the time he made it and that it had a material bearing on the criminality of the maker of the statement, but also that he was compelled to make that statement. 'Compulsion' in the context' must mean what in law is called 'duress'. In *The Dictionary of English Law* by Earl Jowitt, 'duress' is explained as follows:—

> *Duress is where a man is compelled to do an act by injury, beating or unlawful imprisonment (sometimes called duress in a strict sense) or by the threat of being killed, suffering some grievous bodily harm, or being unlawfully imprisoned (sometimes called menace, or duress 'permines'). Duress also includes threatening, beating or imprisonment of the wife, parent or child of a person.*

The compulsion in this sense is a physical objective act and not the state of mind of the person making the statement, except where the mind has been so conditioned by some extraneous process as to render the making of the statement involuntary and, therefore, exhorted. Hence, the mere asking by a police officer investigating a crime against a certain individual to do a certain thing is not compulsion within the meaning of Article 20(3). Hence, the mere fact that the accused person, when he made the statement in question was in police custody would not, by itself, be the foundation for an inference of law that the accused was compelled to make the statement. Of course, it is open to an accused person to show that while he was in police custody at the relevant time, he was subjected to treatment which, in the circumstances of the case, would lend itself to the inference that compulsion was in fact exercised. In other words, it will be a question of fact in each case to be determined by the court on weighing the facts and circumstances disclosed in the evidence before it.

7. AIR 1954 SC 300.
8. AIR 1960 SC 756.

In view of these considerations, we have come to the following conclusions:—

1. ***An accused person cannot be said to have been compelled to be a witness against himself simply because he made a statement while in police custody, without anything more. In other words, the mere fact of being in police custody at the time when the statement in question was made would not, by itself, as a proposition of law, lend itself to the inference that the accused was compelled to make the statement, though that fact, in conjunction with other circumstances disclosed in evidence in a particular case, would be a relevant consideration in an enquiry whether or not the accused person had been compelled to make the impugned statement.***
2. ***The mere questioning of an accused person by a police officer, resulting in a voluntary statement, which may ultimately turn out to be incriminatory, is not 'compulsion'.***
3. ***To be a 'witness' is not equivalent to 'furnishing evidence' in its widest significance; that is to say, as including not merely making of oral or written statements but also the production of documents or giving materials which may be relevant at a trial to determine the guilt or innocence of the accused.***
4. ***Giving thumb impressions or impressions of foot or palm or fingers or specimen writings or showing parts of the body by way of identification are not included in the expression 'to be a witness.'***
5. ***To be a witness means imparting knowledge in respect of relevant facts by an oral statement or a statement in writing, made or given in court or otherwise.***
6. ***To be a witness in its ordinary grammatical sense means giving oral testimony in court. Case-law has gone beyond this strict literal interpretation of the expression which may now bear a wider meaning, namely, bearing testimony in court or out of court by a person accused of an offence, orally or in writing.***
7. ***To bring the statement in question within the prohibition of Article 20(3), the person accused must have stood in the character of an accused person at the time he made the statement. It is not enough that he should become an accused, any time after the statement has been made.***

37.1.1 Minority Judgment

We can, therefore, find no justification for thinking that "to be a witness" in Article 20(3) means to impart personal knowledge and find no reason for departing from what this court said in *Sharma's* case[9], that 'to be a witness' is nothing more than 'to furnish evidence", and such evidence can be furnished through lips or by production of a thing or of a document or in other modes.

The question then is: Is an accused person furnishing evidence when he is giving his specimen handwriting or impressions of his fingers or palm or foot?

It appears to us that he is. For these are relevant facts, within the meaning of section 9 and section 11 of the Evidence Act. Just as an accused person is furnishing evidence and by doing so, is being a witness when he makes a statement that he did something, or saw something, so also he is giving evidence and so is being a "witness" when he produces a letter the contents of which are relevant under section 10, or is producing the plan of a house where a burglary has been committed, or is giving his specimen handwriting or impressions of his finger, palm or foot. It has to be noticed, however, that Article 20(3) does not say that an accused person

9. AIR 1954 SC 300.

shall not be compelled to be a witness. It says that such a person shall not be compelled to be a witness against himself. The question that arises, therefore, is: Is an accused person furnishing evidence against himself, when he gives his specimen handwriting, or impressions of his fingers, palm or foot? The answer to this must, in our opinion, be in the negative.

The matter becomes clear, when we contrast the giving of such handwriting or impressions, with, say, the production of a letter admissible in evidence under section 10 or the production of the plan of a burgled house. In either of these two latter cases, the evidence given tends by itself to incriminate the accused person. But the evidence of specimen handwriting or the impressions of the accused person's fingers, palm or foot, will incriminate him, only if on comparison of these with certain other handwritings or certain other impressions, the identity between the two sets is established. By themselves, these impressions or the handwritings do not incriminate the accused person, or even tend to do so. That is why it must be held that by giving these impressions or specimen handwriting, the accused person does not furnish evidence against himself. So, when an accused person is compelled to give a specimen handwriting or impressions of his finger, palm or foot, it may be said that he has been compelled to be a witness; it cannot, however, be said that he has been compelled to be a witness against himself.

This view, it may be pointed out, does not in any way militate against the policy underlying the rule against 'testimonial compulsion' we have already discussed above. There is little risk, if at all, in the investigator or the prosecutor being induced to lethargy or inaction because he can get such handwriting or impressions from an accused person. For, by themselves they are of little or of no assistance to bring home the guilt of an accused. Nor is there any chance of the accused to mislead the investigator into wrong channels by furnishing false evidence. For, it is beyond his power to alter the ridges or other characteristics of his hand, palm or finger or to alter the characteristics of his handwriting.

We agree, therefore, with the conclusion reached by the majority of the Bench that there is no infringement of Article 20(3) of the Constitution by compelling an accused person to give his specimen handwriting or signature; or impressions of his fingers, palm or foot to the investigating officer or under orders of a court for the purpose of comparison under the provisions of section 73 of the Indian Evidence Act; though we have not been able to agree with the view of our learned Brethren that 'to be a witness' in article 20(3) should be equated with the imparting of personal knowledge or that an accused does not become a witness when he produces some document not in his own handwriting even though it may tend to prove facts in issue or relevant facts against him.

37.2 EXPERT EVIDENCE[10] u/s 45, IEA

Author's Summary

The Apex Court has delineated the elements of expert evidence. Supreme Court said that its first requirement is to decide whether the given evidence is outside the knowledge and experience of layman such as scientific question, where the central role of expert cannot be disputed. The other requirements of the expert evidence are that the expert must be within a recognized field of expertise, the evidence must be based on reliable principles, and the expert must be qualified in that discipline. It stressed that expert evidence is of advisory character to courts and they must form its own assessment on the total evidence.

Highlights italicised

10. *Ramesh Chandra Agrawal v Regency Hospital Ltd*, AIR 2010 SC 806 : 2009 AIR SCW 7038 : (2009) 9 SCC 709.

Relevant Extracts

The law of evidence is designed to ensure that the court considers only that evidence which will enable it to reach a reliable conclusion. *The first and foremost requirement for an expert evidence to be admissible is that it is necessary to hear the expert evidence. The test is that the matter is outside the knowledge and experience of the lay person.* Thus, there is a need to hear an expert opinion where there is a medical issue to be settled. The scientific question involved is assumed to be not within the court's knowledge. Thus, cases where the science involved is highly specialized and perhaps even esoteric, the central role of expert cannot be disputed.

The other requirements for the admissibility of expert evidence are:

(i) that the expert must be within a recognised field of expertise,

(ii) that the evidence must be based on reliable principles, and

(iii) that the expert must be qualified in that discipline.

[See *Errors, Medicine and the Law, Alan Merry and Alexander McCall Smith,* 2001 Ed., Cambridge University Press, p. 178]

(12) Section 45 of the Indian Evidence Act speaks of expert evidence. It reads as under:

45. Opinions of experts – When the Court has to form an opinion upon a point of foreign law, or of science, or art, or as to identity of handwriting or finger-impressions, the opinions upon that point of persons specially skilled in such foreign law, science or art, or in questions as to identity of handwriting or finger impressions, are relevant facts. Such person called experts.

Illustrations

(a) The question is, whether the death of *A* was caused by poison. The opinions of experts as to the symptoms produced by the poison by which *A* is supposed to have died, are relevant.

(b) The question is whether *A*, at the time of doing a certain act, was by reason of unsoundness of mind, in capable of knowing the nature of the act, or that he was doing what was either wrong or contrary to law. The opinions of experts upon the question whether the symptoms exhibited by *A* commonly show unsoundness of mind, and whether such unsoundness of mind usually renders persons incapable of knowing the nature of the acts which they do, or knowing that what they do is either wrong or contrary to law, are relevant.

(c) The question is, whether a certain document was written by *A*. Another document is produced which is proved or admitted to have been written by *A*. The opinion of experts on the question whether the two documents were written by the same person or by different persons are relevant. The importance of the provision has been explained in the case of *State of Himachal Pradesh v Jai Lal*, (1999) 7 SCC 280. It is held, that, section 45 of the Evidence Act which makes opinion of experts admissible lays down, that, when the court has to form an opinion upon a point of foreign law, or of science, or art, or as to identity of handwriting or finger impressions, the opinions upon that point of persons specially skilled in such foreign law, science or art, or in questions as to identity of handwriting, or finger impressions are relevant facts.

Therefore, in order to bring the evidence of a witness as that of an expert it has to be shown that he has made a special study of the subject or acquired a special experience therein or in other words that he is skilled and has adequate knowledge of the subject. It is not the province of the expert to act as a Judge or Jury. It is stated in Titli v Jones, AIR 1934 All 237, that the real function of the expert is to put before the court all the materials, together with reasons which induce him to come to the conclusion, so that the court, although not an expert, may form its own judgment by its own observation of those materials. An expert is not a witness of fact and his evidence is really of an advisory character. The duty of an expert witness is to furnish the Judge with the necessary scientific criteria for testing the accuracy of the conclusions so as

to enable the Judge to form his independent judgment by the application of these criteria to the facts proved by the evidence of the case. The scientific opinion evidence, if intelligible, convincing and tested becomes a factor and often an important factor for consideration along with other evidence of the case.

The credibility of such a witness depends on the reasons stated in support of his conclusions and the data and material furnished which form the basis of his conclusions. (See Malay Kumar Ganguly v Dr. Sukumar Mukherjee) [Criminal Appeal Nos. 1191-1194 of 2005 alongwith Civil Appeal No. 1727 of 2007, decided on 7-8-2009].

(16) In the case of *State of Maharashtra v Damu Gopinath Shinde,* 2000 AIR SCW 1617 : 2000 Cr LJ 2301 : AIR 2000 SC 1691 (1700), it has been laid down that without examining the expert as a witness in Court, no reliance can be placed on opinion alone. In this regard, it has been observed in *State (Delhi Administration) v Pali Ram,* AIR 1979 SC 14 : 1979 Cr LJ 17 : (1979) 2 SCC 158 that "no expert would claim today that he could be absolutely sure that his opinion was correct, expert depends to a great extent upon the materials put before him and the nature of question put to him."

(17) In the Article "Relevancy of Expert's Opinion" ***it has been opined that the value of expert opinion rests on the facts on which it is based and his competency for forming a reliable opinion. The evidentiary value of the opinion of expert depends on the facts upon which it is based and also the validity of the process by which the conclusion is reached. Thus, the idea that is proposed in its crux means that the importance of an opinion is decided on the basis of the credibility of the expert and the relevant facts supporting the opinion so that its accuracy can be cross checked. Therefore, the emphasis has been on the data on basis of which opinion is formed. The same is clear from following inference: "Mere assertion without mentioning the data or basis is not evidence, even if it comes from expert. Where the experts give no real data in support of their opinion, the evidence even though admissible, may be excluded from consideration as affording no assistance in arriving at the correct value."***

37.3 "SCIENCE" AND "ART" EVIDENCE[11] u/s 45 INDIAN EVIDENCE ACT

Author's Summary

The SC has stressed that the ramifications of the word **'science'** and **'art'** are wide:

"each of the words 'science' and 'art' has to be construed widely to include within its ambit the opinion of an expert in each branch of these subjects, wherever the court has to form an opinion *upon a point relating to any aspect of science or art."*

Highlights italicised

Relevant Extracts

In the Indian Evidence Act, 1872, Chapter II relating to 'Relevancy of Facts' contains sections 5 to 55 and therein under the heading 'Opinions of Third Persons, when relevant' are sections 45 to 51. Section 45 reads thus:

> *Opinions of experts.*—When the court has to form an opinion upon a point of foreign law, or of science, or art, or as to identity of handwriting [or finger impressions] (Ins. by Act 5 of 1899, section 3), the opinions upon that point of persons specially skilled in such foreign law, science or art, [or in questions as to identity of handwriting] (Ins. by Act 18 of 1872, section 4), [or finger impressions] (Ins. by Act 5 of 1899, section 3), are relevant facts.
>
> Such persons are called experts.

11. *State (through CBI/New Delhi) v SJ Choudhary*, AIR 1996 SC 1491 : 1996 AIR SCW 1128 : 1996 Cr LJ 1713.

Illustration (c) to section 45 is as under:

(c) The question is, whether a certain document was written by *A*. Another document is produced which is proved or admitted to have been written by *A*.

The opinions of experts on the question of whether the two documents were written by the same person or by different persons are relevant.

The plain meaning of section 45 is that the court in order to form an opinion upon a point of foreign law, or of science, or art, or as to identity of handwriting, or finger impressions can treat the opinion upon that point of person specially skilled in such foreign law, science or art, or in questions as to identity of handwriting, or finger impressions as relevant facts.

In other words, the opinion of persons specially skilled in such foreign law science, or art, or questions as to the identity of handwriting or finger impression, called experts therein, are relevant facts. The opinion of such experts is admissible in evidence as relevant facts by virtue of section 45 of the Evidence Act.

However, the expression 'science', or in section 45 in addition to the expressions 'foreign law' and 'handwriting' use in the section as originally enacted, and the expression 'finger impressions' inserted in 1899 is sufficient to indicate that the expression 'science, or art' therein is of wide import. This expression 'science, or art' cannot therefore, have a narrow meaning in section 45 and each of the words 'science' and 'art' has to be construed widely to include within its ambit the opinion of an expert in each branch of these subjects, wherever the court has to form an opinion upon a point relating to any aspect of science or art.

The meaning of the word 'science' as understood ordinarily with reference to its dictionary meaning must be attributed to the word as used in section 45 of the Indian Evidence Act. Some of the meanings given in the dictionaries are:

The Oxford Encyclopaedic English Dictionary:

Science... a. systematic and formulated knowledge, esp. of a specified type or on a specified subject (political science), b. the pursuit or principles of this....

The New Shorter Oxford English Dictionary, Vol. 2:

Science..... 2a. Knowledge acquired by study acquaintance with or mastery of a department of learning... 3a. A particular branch of knowledge or study; a recognised department of learning....

Collins Dictionary of the English Language:

Science 1. the systematic study of the nature and behaviour of the material and physical universe, based on observation, experiment, and measurement, and the formulation of laws to describe these facts in general terms. 2. the knowledge so obtained or the practice of obtaining it. 3. any particular branch of this knowledge: the pure and applied sciences. 4. any body of knowledge organised in a systematic manner. 5. skill or technique...

37.4 EXPERT VERSUS OCULAR EVIDENCE[12]

Author's Summary

It is a case of murder where the IO and the Medico-legal doctor showed extreme degree of dereliction of duty. The IO lost the material evidence. The doctor refused to record injuries on the person of the deceased. SC felt that the dereliction of duties was deliberate. They discarded their evidence.

The eyewitness evidence was reliable and sufficient. They convicted the culprit. On the eyewitness accounts. SC wrote to government to take action against the derelicts.

Highlights italicised

12. *Dayal Singh v State of Uttaranchal,* AIR 2012 SC 3046 : (2012) 8 SCC 263 : 2012 Cr LJ 4323. [DOJ: 3-8-2012].

Relevant Extracts (Verbatim)

There were three injuries on the person of the deceased, Pyara Singh and prepared Inquest Report *vide* Ex. Ka-6 recording his opinion that the deceased died on account of the injuries found on his body. After preparing the site plan, Ext. Ka-10, he also wrote a letter to the Superintendent, Civil Hospital, Haldwani for post-mortem, being Exhibit Ka-9. The dead body was taken to the said hospital by Constable Chandrapal Singh, PW 7. Dr. C.N. Tewari, PW-3, a medical officer in the Civil Hospital, Haldwani, performed the post-mortem upon the body of the deceased and did not find any ante-mortem or post-mortem injuries on the dead body. On internal examination, he did not find any injuries and could not ascertain the cause of death. Further, he preserved the viscera and gave the post-mortem report, Exhibit Ka-4. After noticing that there was no injury or abnormality found upon external and internal examination of the dead body, the doctor in his report recorded as under:

> Viscera in sealed jars handed over to the accompanying Constables.
>
> Jar No. 1 sample preservative saline water.
>
> Jar No. 2 Pieces of stomach
>
> Jar No. 3 Pieces of liver, spleen and kidney.
>
> Death occurred about one day back.
>
> Cause of death could not be ascertained. Hence, viscera preserved.

It appears from the record that the deceased's viscera, which allegedly was handed over by doctor to the police, was either never sent to the Forensic Science Laboratory (for short, the 'FSL') for chemical examination, or if sent, the report thereof was neither called for nor proved before the Court. In fact, this has been left to the imagination of the Court. Considering the ocular and other evidence produced by the prosecution, the learned trial court *vide* its judgment of conviction and order of sentence, both dated 29th June, 1990, found the accused persons guilty of offences under section 302 read with section 34 IPC as well as under section 323 read with section 34 IPC. The trial court, while dealing with the arguments of the accused for application of section 34, as well as the submission that the witnesses had not attributed specific role to the respective accused persons, held as under:

> The attack was premeditated and the accused had come fully prepared to do the overt act. The injury was caused on the head of the deceased which is a vital part of the body at which it was aimed by employing lathi, it was clear that the accused persons had intended to cause death by giving blow on vital part of the body of the deceased. After receiving the injuries, the deceased fell down and even thereafter he was attacked by the accused persons and he died on the spot immediately. The expert witness is expected to put before the Court all materials inclusive of the data which induced him to come to the conclusion and enlighten the court on the technical aspect of the case by examining the terms of science, so that the court, although not an expert, may form its own judgment on those materials after giving due regard to the expert's opinion, because once the expert opinion is accepted, it is not the opinion of the medical officer but that of the Court. See *Madan Gopal Kakkad v Naval Dubey*, (1992) 2 SCR 921 : (1992) 3 SCC 204 : 1992 AIR SCW 1480].

31. Profitably, a reference to the value of an expert in the eye of law can be assimilated as follows:

> *The essential principle governing expert evidence is that the expert is not only to provide reasons to support his opinion but the result should be directly demonstrable. The court is not to surrender its own judgment to that of the expert or delegate its authority to a third party, but should assess his evidence like any other evidence. If the report of an expert is slipshod,*

inadequate or cryptic and the information of similarities or dissimilarities is not available in his report and his evidence in the case, then his opinion is of no use. It is required of an expert whether a government expert or private, if he expects, his opinion to be accepted to put before the court the material which induces him to come to his conclusion so that the court though not an expert, may form its own judgment on that material. If the expert in his evidence as a witness does not place the whole lot of similarities or dissimilarities, etc., which influence his mind to lead him to a particular conclusion which he states in the court then he fails in his duty to take the court into confidence. The court is not to believe the ipse dixit *of an expert. Indeed the value of the expert evidence consists mainly on the ability of the witness by reason of his special training and experience to point out the court such important facts as it otherwise might fail to observe and in so doing the court is enabled to exercise its own view or judgment respecting the cogency of reasons and the consequent value of the conclusions formed thereon. The opinion is required to be presented in a convenient manner and the reasons for a conclusion based on certain visible evidence, properly placed before the Court. In other words the value of expert evidence depends largely on the cogency of reasons on which it is based.*

[See: *Forensic Science in Criminal Investigation & Trial* (4th Edn) by B.R. Sharma]

32. The purpose of expert testimony is to provide the Trier of fact with useful, relevant information. The overwhelming majority rule in the United States, is that an expert need not be a member of a learned profession. Rather, experts in the United States have a wide range of credentials and testify regarding a tremendous variety of subjects based on their skills, training, education or experience. The role of the expert is to apply or supply specialized, valuable knowledge that lay jurors would not be expected to possess. An expert may present the information in a manner that would be unacceptable with an ordinary witness. The common law tried to strike a balance between the benefits and dangers of expert testimony by allowing expert testimony to be admitted only if the testimony were particularly important to aid the trier of fact. Even in the United States, if the helpfulness of expert testimony is substantially outweighed by the risk of unfair prejudice, confusion or waste of time, then the testimony should be excluded under the relevant Rules, and State equally balanced. Expert testimony on any issue of fact and significance of its application has been doubted by the scholars in the United States. Even under the law prevalent in that country, the opinion of an expert has to be scientific, specific and experience based. Conflict in expert opinions is a well prevalent practice there. The skill and experience of an expert is the ethos of his opinion, which itself should be reasoned and convicting. Not to say that no purview would be possible, but if the view of the expert has to find due weightage in the mind of the Court, it has to be well authorised and convincing.

Dr. C.N. Tewari was expected to prepare the post-mortem report with appropriate reasoning and not leave everything to the imagination of the Court. He created a serious doubt as to the very cause of death of the deceased. His report apparently shows an absence of skill and experience and was, in fact, a deliberate attempt to disguise the investigation.

We really need not reiterate various judgments, which have taken the view that the purpose of an expert opinion is primarily to assist the Court in arriving at a final conclusion. Such report is not binding upon the Court. The Court is expected to analyse the report, read it in conjunction with the other evidence on record and then form its final opinion as to whether such report is worthy of reliance or not. Just to illustrate this point of view, in a given case, there may be two diametrically contradictory opinions of handwriting experts and both the opinions may be well reasoned. In such case, the Court has to critically examine the basis, reasoning, approach and experience of the expert to come to a conclusion as to which of the two reports can be safely relied upon by the Court.

The assistance and value of expert opinion is indisputable, but there can be reports which are, ex facie, incorrect or deliberately so distorted as to render the entire prosecution case unbelievable. But if such eyewitnesses and other prosecution evidence are trustworthy, have credence and are consistent with the eye version given by the eye-witnesses, the Court will be well within its jurisdiction to discard the expert opinion. An expert report, duly proved, has its evidentiary value but such appreciation has to be within the limitations prescribed and with careful examination by the Court. A complete contradiction or inconsistency between the medical evidence and the ocular evidence on the one hand and the statement of the prosecution witnesses between themselves on the other, may result in seriously denting the case of the prosecution in its entirety but not otherwise.[13]

37.5 EXTENSIVE/EXEMPLARY USE OF FORENSIC SCIENCE[14]

(Rarest of the rare cases: Nirbhaya Rape-murder)

Author's Summary

It is a landmark judgment where the judges have utilised Forensic Science extensively for the dissemination of justice in this case of inhuman brutal rape- murder case.

The facts of the case are that the victim Nirbhaya, along with her friend (PW- 1) boarded a bus going to Dwarka/Palam. They noticed that six persons were already inside the bus. The accused did not allow anyone else to board. The bus moved and the inside lights of the bus were put off. A few minutes later, three persons (identified as accused Ram Singh, Akshay and a juvenile) started to abuse. Pw-1 objected that led to altercation. The two other joined the melee. PW-1 was beaten badly. He became immobile. Nirbhaya was raped by all the six mauled, her so beastly/brutally that she died a few days later, in spite of the best medical help.

The police did an excellent job of locating and using all the available scientific evidence (CCTV footage for the identification of bus, fingerprints, bite marks, hair, DNA to inter-link the victims and the culprits) and presented an airtight case.

All the courts (trial/ high courts and the Supreme Court) appreciated the evidence. They found it **'rarest of the rare cases'** and sentenced them to death, excluding the juvenile.

Highlights italicised

Relevant Extracts (Verbatim)

> The prosecution case, as projected, is that on 16.12.2012, the deceased, 'Nirbhaya' (not her real name), had gone with her friend, the informant, PW- 1, to the PVR situated in Select City Walk Mall, Saket to watch a movie. After the show was over, about 8:30 p.m., they took an auto and reached Munirka bus stand wherefrom they boarded a white coloured chartered bus [DL- 1P-C-0149, Ext.P1] which was bound to Dwarka/Palam Road, as a boy in the bus was calling for commuters for the said destination. As per the version of the informant, PW-1, the friend of the prosecutrix, the bus had yellow and green lines/stripes and the word "Yadav" was written on it.

13. *Madan Gopal Kakkad v Naval Dubey*, 1992 AIR SCW 1480 : (1992) 3 SCC 204 : (1992) 2 SCR 921.
14. *Mukesh v State for NCT Delhi*, Criminal Appeal Nos. 607-608 of 2017, SC, decided on 5 May 2017. Bench: Dipak Misra, R. Banumathi, Ashok Bhushan.
    The Supreme Court has discussed the evidence relating to DNA, Bite Marks, and Fingerprint lucidly, with numerous case citations.

After both of them had entered the bus, they noticed that six persons were already inside the bus, four in the cabin of the driver and two behind the driver's cabin. The deceased and the informant sat on the left side in the row of two-seaters and paid the fare of twenty rupees as demanded. Before they could get the feeling of a safe journey (though not a time-consuming journey), a feeling of lonely suffocation and a sense of danger barged in, for the accused persons did not allow anyone else to board and the bus moved and the lights inside the bus were put off. With the lights being put off, the darkness and the fear of the unexpected darkness ruled.

A few minutes later, three persons (who have been identified as accused Ram Singh, Akshay and a young boy, who has been treated as a juvenile in conflict with the law) came out of the driver's cabin and started to abuse PW- 1. The young companion of the deceased raised opposition to the abuse that led to an altercation which invited the other two who were sitting outside the driver's cabin to join.

The spirit to oppose and the duty to save the prosecutrix had to die down and perilously succumb to the assault by the accused persons with the iron rods that caused injuries to his head, both the legs and other parts of the body and the consequence was that he fell on the floor of the bus to hear the painful cries of the lady who, he knew, was being treated as an object, an article for experimentation and prey to the pervert proclivity of the six but could do nothing except to hear unbearable cries made in agony and pain. His spirit was dead, and bound to.

5. As the prosecution story further unfurls, the two accused persons, namely, Pawan and Vinay, pinned the young man down and robbed the victims of their mobiles besides robbing the informant of his purse carrying a Citi Bank credit card, ICICI Bank Debit Card, his identity card issued by his employer-company, metro card, a sum of rupees one thousand, his Titan Watch, a golden ring studded with jewels and a silver ring studded with pearl, black colour Hush Puppies shoes, black colour Numero Uno jeans, a grey colour pullover and a brown colour blazer. As per the version of the prosecution, PW-1 was carrying two mobiles and the prosecutrix was carrying only one, and the accused snatched away all the three mobiles.

6. The overpowering was not meant to satisfy the avarice. As the accusations proceed, after the informant was overpowered, as it could only have a singular result, the accused persons, namely, Ram Singh, Akshay and the Juvenile in Conflict with Law (JCL) took the prosecutrix to the rear side of the bus and she was raped by them, one after the other.

7. After committing rape, the accused Ram Singh (since deceased), accused Akshay and the JCL came towards the informant, PW-1, and nailed him down; then the accused Vinay and accused Pawan went to the rear side of the bus and committed rape on the prosecutrix, one by one. PW-1 noticed that earlier the bus was moving at fast speed but after sometime, he felt that the speed of the bus was reduced and he saw that the accused Mukesh, who was driving the bus, came near him and hit him with the rod and he also went to the rear side of the bus and raped the prosecutrix.

The prosecutrix was brutally gang raped by the accused one after the other and she was also subjected to unnatural sex. Her private parts and her internal organs were seriously injured by inserting an iron rod and hand in the rectal and vaginal region. As per PW-1, he had heard the cries of the prosecutrix like "chod do, bachao". PW-1 could hear the prosecutrix shouting in a loud oscillating voice. The prosecutrix was carrying a grey colour purse having an Axis Bank ATM card and other belongings.

The accused persons robbed her of her belongings and stripped her. They also took away the clothes of the informant while beating him with iron rods. The accused were exhorting that both the victims be not left alive. The accused then tried to throw both the informant and the prosecutrix out of the moving bus from its rear door but could not open it and so, they brought them to the front door and threw them out of the moving bus at National Highway No. 8, Hotel Delhi 37, Mahipalpur flyover by the side of the road.

8. As indicated earlier, the prosecutrix and PW-1 were noticed by PW-72, Raj Kumar, who heard the voice of 'bachao, bachao' from the left side of the road near a milestone opposite to Hotel Delhi 37. PW-72 saw PW-1 and the prosecutrix sitting naked having blood all around. Immediately thereafter, PW-72, Raj Kumar, informed PW-70, Ram Pal, who was in the Control Room, requesting him to call PCR. PW-70, Ram Pal, of EGIS Infra Management India (P) Limited, dialled 100 No. and even asked his other patrolling staff to reach the spot.

9. About 10:24 p.m., PW-73, H.C. Ram Chander, who was in charge of PCR van Zebra 54, received information about the incident and the lying of victims in a naked condition near the foot of Mahipalpur flyover towards Dhaula Kuan opposite GMR Gate. PW-73 reached the spot and found the victims. He got the crowd dispersed and brought a bottle of water and a bed sheet from the nearby hotel and tore the same into two parts and gave it to both the victims to cover themselves.

Collection of samples and identity of accused persons

32. The blood sample of the informant was collected by Dr. Kamran Faisal, PW-15, Safdarjung Hospital, on 25.12.2012 and was handed over to SI Pratibha Sharma, PW-80, vide seizure memo Ex.PW-15/A by Constable Suresh Kumar, PW-42. Similarly, as mentioned earlier, PW-49, Dr. Rashmi Ahuja, had collected certain samples from the person of the prosecutrix which are reflected in Ex.PW-49/A from point B to B. All the samples were collected by Inspector Raj Kumari, PW-59, vide seizure memo Ex.PW-59/A and were handed over to PW-80, SI Pratibha Sharma, at Safdarjung Hospital in the morning of 17.12.2012.

Also the samples of gangrenous bowels of the prosecutrix were taken on 24.12.2012 and were handed over to SI Gajender Singh, PW-55, who seized the same vide seizure memo Ex.PW-11/A. All the samples were deposited with the MHC(M) and were not tampered with in any manner. A specimen of scalp hair of the prosecutrix was also taken on 24.12.2012 by Dr. Ranju Gandhi, PW-29, and was handed over to PW- 80, SI Pratibha Sharma, vide seizure memo Ex.PW-29/A.

33. The accused were also subjected to medical examination and samples were taken from their person which were sent for DNA analysis.

34. *DNA analysis was done at the behest of PW-45, Dr. B.K. Mohapatra, Sr. Scientific Officer, Biology, CFSL, CBI, and Biological Examination and DNA profiling reports were prepared which are exhibited as Ex. PW-45/A-C. The report, after analysing the DNA profiles generated from the known samples of the prosecutrix, the informant, and each of the accused, concluded that: "An analysis of the above shows that the samples were authentic and established the identities of the persons mentioned above beyond reasonable doubt."*

35. On 17.12.2012 and 18.12.2012, a team of experts from the CFSL went to Thyagraj Stadium and ***lifted chance prints from the bus*** in question, Ex.P-1. On 28.12.2012, PW-78, Inspector Anil Sharma of P.S. Vasant Vihar, the then S.H.O. of Police Station Vasant Vihar, requested the Director, CFSL, for taking digital palm prints and foot prints of all the accused persons vide his letter Ex.PW-46/C. Pursuant to the said request made by PW-78, Inspector Anil Sharma, the CFSL, on 31.12.2012, took the finger/palm prints and foot prints of the accused persons at Tihar Jail.

After comparing the chance prints lifted from the bus with the finger prints/palm prints and foot prints of all the accused persons, PW-46, Shri A.D. Shah, Senior Scientific Officer (Finger Prints), CFSL, CBI submitted his report Ex.PW- 46/D. In the report, the chance prints of accused Vinay Sharma were found to have matched with those on the bus in question.

36. ***Bite mark analysis*** was also undertaken by the investigative team to establish the identity and involvement of the accused persons. PW-66, Asghar Hussain, on the instructions of the I.O., S.I. Pratibha Sharma, had taken 10 photographs of different parts of the body of the prosecutrix at SJ Hospital on 20.12.2012 between 4:30 p.m. and 5:00 p.m. which were marked as Ex.PW-66/B (Colly.) [10 photographs of 5" x 7" each] and Ex.PW-66/C (Colly.) [10 photographs of 8" x 12" each]. PW-66 also proved in Court the

certificate provided by him in terms of Section 65-B of the Evidence Act in respect of the photographs, Ex. PW-66/A.

Thereafter, PW-18, SI Vishal Choudhary, collected the photographs and the dental models from Safdarjung Hospital on 01.01.2013 and duly deposited the same in the malkhana after he, PW-18, had handed them over to the S.H.O. Anil Sharma, PW-78. The same were later entrusted to S.I. Vishal Choudhary, PW-18 on 02.01.2013, which is proved vide RC No.183/21/12 and exhibited as Ex.PW-77/V. PW-71, Dr. Ashith B. Acharya, submitted the final report in this regard which is exhibited as Ex. PW-71/C. In the said report, he has concluded that at least three bite marks were caused by accused Ram Singh whereas one bite mark has been identified to have been most likely caused by accused Akshay.

Thereafter, on 03.01.2013, the report of the CFSL was received. In fact, the trial court had assured itself of the correct identification of the bus by playing the said CCTV footage shown in the pen drive, Ex.PW-67/1, and the CD, Ex.PW-67/2, during the cross-examination of PW-67, Pramod Jha.

98. Learned counsel Mr. Singh has asserted that bus, Ex. P-1, has been falsely implicated in the present case as is evidenced from the recovery of the CCTV footage. In an attempt to discredit the CCTV footage, he pointed out that only the CCTV recording alleged to be of this bus was recorded and not of all other white buses that had 'Yadav' written on them. The learned counsel for the defence subsequently maintained that the CCTV footage cannot be relied upon as the same has been tampered with by the investigating officers.

99. PW-76, Gautam Roy, HOD, Computer Cell, Forensic Division, has testified that on 02.01.2013, he had received two sealed parcels sealed with the seal of PS and the seals tallied with the specimen seals provided. He marked the blue coloured pen drive found in parcel No.1 as Ex.1 and the Moser Baer CD found in the second parcel as Ex.2. He further testified that both the exhibits were played by him on the computer and the bus was seen twice, at 9:34 p.m. and 9:54 p.m.

He had photographed all these three by freezing the pen drive and the CD and these photographs were compared by him with the photographs taken by the photographer, PW-79, P.K. Gottam, which he had summoned. The witness testified that he had prepared the three comparison charts in this regard as Ex.PW-76/B, PW-76/C and PW-76/D, and his detailed report as Ex.PW-76/E.

The footage taken in a CD and pen drive was sealed in PW-67's presence and as the recording was automatic data being fed on regular basis into the hard disk, the question of tampering with the same could not arise. PW-79, P.K. Gottam, from CFSL, CBI, has stated in his examination that he took photographs of the bus bearing No.DL- 1P-C-0149 parked at Thyagraj Stadium, INA, New Delhi from different angles on 17.12.2012 and 18.12.2012 and handed over the same to PW-76. The said photographs were marked as B1 in Ex.PW-76/B; as C1 and C2 in Ex.PW-76/C; and as D1 in Ex.PW-76/D. He has deposed as to the genuineness of the photographs by deposing that the software used for developing the photographs was tamper proof.

100. Once it is proved before the court through the testimony of the experts that the photographs and the CCTV footage are not tampered with, there is no reason or justification to perceive the same with the lens of doubt. The opinion of the CFSL expert contained in the CFSL report marked as Ex.PW-76/E authenticates that there was no tampering or editing in both the exhibits, Ex.P-67/1 and Ex.P- 67/2, and that a bus having identical patterns as the one parked at Thyagraj Stadium is seen in the CCTV footage, which includes the word "Yadav" written on one side, "back side dent (left)" and absence of wheel cover on the front left side. The contents of the report is also admitted to be true by its author, PW-76, Gautam Roy. Quite apart from that, it is perceptible that the High Court, in order to satisfy itself, had got the CCTV footage played during the hearing and found the same to be creditworthy and acceptable. 157.

207. Having dealt with the aspect pertaining to insertion of rod, it is apposite to advert to the medical evidence and post mortem report. We have, while dealing with other

aspects, referred to certain aspects including **DNA analysis** of medical evidence but the same requires to be critically dealt with as the prosecution has placed heavy reliance upon it.

208. DNA is the abbreviation of Deoxyribo Nucleic Acid. It is the basic genetic material in all human body cells. It is not contained in red blood corpuscles. It is, however, present in white corpuscles. It carries the genetic code. DNA structure determines human character, behaviour and body characteristics. DNA profiles are encrypted sets of numbers that reflect a person's DNA makeup which, in forensics, is used to identify human beings. DNA is a complex molecule. It has a double helix structure which can be compared with a twisted rope 'ladder'.

209. The nature and characteristics of DNA had been succinctly explained by Lord Justice Phillips in Regina v Alan James Doheny & Gary Adams[83]. In the above case, the accused were convicted relying on results obtained by comparing DNA profiles obtained from a stain left at the scene of the crime with DNA profiles obtained from a sample of blood provided by the appellant. In the above context, with regard to DNA, the following was stated by Lord Justice Phillips: "Deoxyribonucleic acid, or DNA, consists of long ribbon-like molecules, the chromosomes, 46 of which lie tightly coiled in nearly every cell of the body. These chromosomes - 23 provided from the mother and 23 from the father at conception, form the genetic blueprint of the body. Different sections of DNA have different identifiable and discrete characteristics.

When a criminal leaves a stain of blood or semen at the scene of the crime it may prove possible to extract from that crime stain sufficient sections of DNA to enable a comparison to be made with the same sections extracted from a sample of blood provided by the suspect. This process is complex and we could not hope to describe it more clearly or succinctly than did Lord Taylor C.J. in the case of Deen (transcript: December 21, 1993), so we shall gratefully adopt his description. "The process of DNA profiling starts with DNA being extracted from the crime stain and also from a sample taken from the suspect. In each case the DNA is cut into smaller lengths by specific enzymes. The fragments produced are sorted according to size by a process of electrophoresis.

This involves placing the fragments in a gel and drawing them electromagnetically along a track through the gel. The fragments with smaller molecular weight travel further than the heavier ones. The pattern thus created is transferred from the gel onto a membrane. Radioactive DNA probes, taken from elsewhere, which bind with the sequences of most interest in the sample DNA are then applied. After the excess of the DNA probe is washed off, an X-ray film is placed over the membrane to record the band pattern. This produces an auto radiograph which can be photographed. When the crime stain DNA and the sample DNA from the suspect have been run in separate tracks through the gel, the resultant auto-radiographs can be compared. The two DNA profiles can then be said either to match or not.""

210. In the United States, in an early case Frye v United States[84], it was laid down that scientific evidence is admissible only if the principle on which it is based is substantially established to have general acceptance in the field to which it belonged. The US Supreme Court reversed the above formulation in Daubert v Merrell Dow Pharmaceuticals, Inc.[85] stating thus: "11. Although the Frye decision itself focused exclusively on "novel" scientific techniques, we do not read the requirements of Rule 702 to apply specially or exclusively to unconventional evidence. Of course, well- established propositions are less likely to be challenged than those that are novel, and they are more handily defended. Indeed, theories that are so firmly established as to have attained the status of scientific law, such as the laws of thermodynamics, properly are subject to judicial notice under Fed.Rule Evid.201.

13. This is not to say that judicial interpretation, as opposed to adjudicative fact finding, does not share basic characteristics of the scientific endeavour: "The work of a judge is in one sense enduring and in another ephemeral... In the endless process of testing and retesting, there is a constant rejection of the dross and a constant retention of whatever is pure and sound and fine." B.Cardozo, The nature of the Judicial Process 178, 179 (1921)."

211. The principle was summarized by Blackmun, J., as follows: "To summarize: "general acceptance" is not a necessary precondition to the admissibility of scientific evidence under

the Federal Rules of Evidence, but the Rules of Evidence-especially Rule 702-do assign to the trial judge the task of ensuring that an expert's testimony both rests on a reliable foundation and is relevant to the task at hand. Pertinent evidence based on scientifically valid principles will satisfy those demands. The inquiries of the District Court and the Court of Appeals focused almost exclusively on "general acceptance," as gauged by publication and the decisions of other courts. Accordingly, the judgment of the Court of Appeals is vacated and the case is remanded for further proceedings consistent with this opinion."

212. After the above judgment, the DNA Test has been frequently applied in the United States of America. In District Attorney's Office for the Third Judicial District et al. v William G. Osborne[86], Chief Justice Roberts of the Supreme Court of United States, while referring to the DNA Test, stated as follows: "DNA testing has an unparalleled ability both to exonerate the wrongly convicted and to identify the guilty. It has the potential to significantly improve both the criminal justice system and police investigative practices.

The Federal Government and the States have recognized this, and have developed special approaches to ensure that this evidentiary tool can be effectively incorporated into established criminal procedure-usually but not always through legislation. ... ... Modern DNA testing can provide powerful new evidence unlike anything known before. Since its first use in criminal investigations in the mid- 1980s, there have been several major advances in DNA technology, culminating in STR technology. It is now often possible to determine whether a biological tissue matches a suspect with near certainty. While of course many criminal trials proceed without any forensic and scientific testing at all, there is no technology comparable to DNA testing for matching tissues when such evidence is at issue."

213. DNA technology as a part of Forensic Science and scientific discipline not only provides guidance to the investigation but also supplies the Court accrued information about the tending features of identification of criminals. The recent advancement in modern biological research has regularized Forensic Science resulting in radical help in the administration of justice. In our country also like several other developed and developing countries, DNA evidence is being increasingly relied upon by courts. After the amendment in the Criminal Procedure Code by the insertion of Section 53A by Act 25 of 2005, DNA profiling has now become a part of the statutory scheme. Section 53A relates to the examination of a person accused of rape by a medical practitioner.

214. Similarly, under Section 164A inserted by Act 25 of 2005, for medical examination of the victim of rape, the description of material taken from the person of the woman for DNA profiling is must. Section 53A sub-section (2) as well as Section 164(A) sub-section (2) are to the following effect:

"Section 53A. Examination of person accused of rape by Medical Practitioner.-

(1) ... ...

(2) The registered medical practitioner conducting such examination shall, without delay, examine such person and prepare a report of his examination giving the following particulars, namely:- the name and address of the accused and of the person by whom he was brought, the age of the accused, marks of injury, if any, on the person of the accused, the description of material taken from the person of the accused for DNA profiling, and other material particulars in reasonable detail. Section 164A. Medical Examination of the victim of rape.-

(1) ... ...

(2) The registered medical practitioner, to whom such woman is sent, shall, without delay, examine her person and prepare a report of his examination giving the following particulars, namely:- the name and address of the woman and of the person by whom she was brought; the age of the woman; the description of material taken from the person of the woman for DNA profiling; marks of injury, if any, on the person of the woman; general mental condition of the woman; and other material particulars in reasonable detail."

215. This Court had the occasion to consider various aspects of DNA profiling and DNA reports. K.T. Thomas, J. in *Kamti Devi (Smt.) v Poshi Ram*[87], observed:

"10. We may remember that Section 112 of the Evidence Act was enacted at a time when the modern scientific advancements with deoxyribonucleic acid (DNA) as well as ribonucleic acid (RNA) tests were not even in contemplation of the legislature. The result of a genuine DNA test is said to be scientifically accurate. ..."

216. In *Pantangi Balarama Venkata Ganesh v State of Andhra Pradesh*[88], a two-Judge Bench had explained as to what is DNA in the following manner:

"41. Submission of Mr Sachar that the report of DNA should not be relied upon, cannot be accepted. What is DNA? It means: "Deoxyribonucleic acid, which is found in the chromosomes of the cells of living beings is the blueprint of an individual. DNA decides the characteristics of the person such as the colour of the skin, type of hair, nails and so on. Using this genetic fingerprinting, identification of an individual is done like in the traditional method of identifying fingerprints of offenders.

The identification is hundred per cent precise, experts opine." There cannot be any doubt whatsoever that there is a need for quality control. Precautions are required to be taken to ensure preparation of high molecular weight DNA, complete digestion of the samples with appropriate enzymes, and perfect transfer and hybridisation of the blot to obtain distinct bands with appropriate control. (See article of Lalji Singh, Centre for Cellular and Molecular Biology, Hyderabad in DNA profiling and its applications.) But in this case there is nothing to show that such precautions were not taken.

42. Indisputably, the evidence of the experts is admissible in evidence in terms of Section 45 of the Evidence Act, 1872. In cross-examination, PW 46 had stated as under: "If the DNA fingerprint of a person matches with that of a sample, it means that the sample has come from that person only. The probability of two persons except identical twins having the same DNA fingerprint is around 1 in 30 billion world population.""

217. In Santosh Kumar Singh v State Through CBI[89], which was a case of a young girl who was raped and murdered, the DNA reports were relied upon by the High Court which was approved by this Court and it was held thus:

"71. We feel that the trial court was not justified in rejecting the DNA report, as nothing adverse could be pointed out against the two experts who had submitted it. We must, therefore, accept the DNA report as being scientifically accurate and an exact science as held by this Court in Kamti Devi v Poshi Ram (supra). In arriving at its conclusions the trial court was also influenced by the fact that the semen swabs and slides and the blood samples of the appellant had not been kept in proper custody and had been tampered with, as already indicated above. We are of the opinion that the trial court was in error on this score. We, accordingly, endorse the conclusions of the High Court on Circumstance 9."

218. In Inspector of Police, Tamil Nadu v John David[90], a young boy studying in MBBS Course was brutally murdered by his senior. The torso and head were recovered from different places which were identified by the father of the deceased. For confirming the said facts, the blood samples of the father and mother of the deceased were taken which were subject to DNA test. From the DNA, the identification of the deceased was proved. Paragraph 60 of the decision is reproduced below: "60. ... The said fact was also proved from the DNA test conducted by PW 77. PW 77 had compared the tissues taken from the severed head, torso and limbs and on scientific analysis he has found that the same gene found in the blood of PW1 and Baby Ponnusamy was found in the recovered parts of the body and that therefore they should belong to the only missing son of PW 1."

219. In *Krishan Kumar Malik v State of Haryana* [91], in a gang rape case when the prosecution did not conduct DNA test or analysis and matching of semen of the appellant-accused with that found on the undergarments of the prosecutrix, this Court held that after the incorporation of Section 53- A in CrPC, it has become necessary for the prosecution to go in for DNA test in such type of cases. The relevant paragraph is reproduced below:

"44. Now, after the incorporation of Section 53-A in the Cr.P.C w.e.f 23.06.2006, brought to our notice by the learned counsel for the respondent State, it has become necessary for the prosecution to go in for DNA test in such type of cases, facilitating the prosecution to prove its case against the accused. Prior to 2006, even without the aforesaid

specific provision in CrPC the prosecution could have still restored to this procedure of getting the DNA test or analysis and matching of semen of the appellant with that found on the undergarments of the prosecutrix to make it a foolproof case, but they did not do so, thus they must face the consequences."

220. In *Surendra Koli v State of Uttar Pradesh* [92], the appellant, a serial killer, was awarded death sentence which was confirmed by the High Court. While confirming the death sentence, this Court relied on the result of the DNA test conducted on the part of the body of the deceased girl. Para 12 is reproduced below:- "12. The DNA test of Rimpa by CDFD, a pioneer institute in Hyderabad matched with that of blood of her parents and brother. The doctors at AIIMS have put the parts of the deceased girls which have been recovered by the doctors of AIIMS together. These bodies have been recovered in the presence of the doctors of AIIMS at the pointing out by the accused Surendra Koli. Thus, recovery is admissible under Section 27 of the Evidence Act."

221. In Mohammed Ajmal Mohammad Amir Kasab alias Abu Mujahid v State of Maharashtra[93], the accused was awarded death sentence on charges of killing large number of innocent persons on 26th November, 2008 at Bombay. The accused with others had come from Pakistan using a boat 'Kuber' and several articles were recovered from 'Kuber'. The stains of sweat, saliva and other bodily secretions on those articles were subjected to DNA test and the DNA test matched with several accused. The Court observed:

222. In Sandeep v State of Uttar Pradesh[94], the facts related to the murder of pregnant paramour/girlfriend and unborn child of the accused. The DNA report confirmed that the appellant was the father of the unborn child. The Court, relying on the DNA report, stated as follows: "67. In the light of the said expert evidence of the Junior Scientific Officer it is too late in the day for the appellant Sandeep to contend that improper preservation of the foetus would have resulted in a wrong report to the effect that the accused Sandeep was found to be the biological father of the foetus received from the deceased Jyoti.

As the said submission is not supported by any relevant material on record and as the appellant was not able to substantiate the said argument with any other supporting material, we do not find any substance in the said submission. The circumstance, namely, the report of DNA in having concluded that accused Sandeep was the biological father of the recovered foetus of Jyoti was one other relevant circumstance to prove the guilt of the said accused."

223. In Rajkumar v State of Madhya Pradesh[95], the Court was dealing with a case of rape and murder of a 14 year old girl. The DNA report established the presence of semen of the appellant in the vaginal swab of the prosecutrix. The conviction was recorded relying on the DNA report. In the said context, the following was stated:

"8. The deceased was 14 years of age and a student in VIth standard which was proved from the school register and the statement of her father Iknis Jojo (PW1). Her age has also been mentioned in the FIR as 14 years. So far as medical evidence is concerned, it was mentioned that the deceased prosecutrix was about 16 years of age. So far as the analysis report of the material sent and the DNA report is concerned, it revealed that semen of the appellant was found on the vaginal swab of the deceased. The clothes of the deceased were also found having appellant's semen spots. The hair which were found near the place of occurrence was found to be that of the appellant."

224. In *Nandlal Wasudeo Badwaik v Lata Nandlal Badwaik* [96], the appellant, father of the child born to his wife, questioned the paternity of the child on the ground that she did not stay with him for the last two years. The Court directed for a DNA test. The DNA result opined that the appellant was not the biological father of the child. The Court also had the occasion to consider Section 112 of the Evidence Act which raises a presumption that birth during marriage is conclusive proof of legitimacy. The Court relied on the DNA test holding the DNA test to be scientifically accurate. The pertinent observations are extracted below:

"19. The husband's plea that he had no access to the wife when the child was begotten stands proved by the DNA test report and in the face of it, we cannot compel the appellant to bear the fatherhood of a child, when the scientific reports prove to the contrary. We

are conscious that an innocent child may not be bastardised as the marriage between her mother and father was subsisting at the time of her birth, but in view of the DNA test reports and what we have observed above, we cannot forestall the consequence. It is denying the truth. "Truth must triumph" is the hallmark of justice.

20. As regards the authority of this Court in Kamti Devi, this Court on appreciation of evidence came to the conclusion that the husband had no opportunity whatsoever to have liaison with the wife. There was no DNA test held in the case. In the said background i.e. non-access of the husband to the wife, this Court held that the result of DNA test "is not enough to escape from the conclusiveness of Section 112 of the Act."

The judgment has to be understood in the factual scenario of the said case. The said judgment has not held that DNA test is to be ignored. In fact, this Court has taken note of the fact that DNA test is scientifically accurate. We hasten to add that in none of the cases referred to above, this Court confronted with a situation in which a DNA test report, in fact, was available and was in conflict with the presumption of conclusive proof of the legitimacy of the child under Section 112 of the Evidence Act.

In view of what we have observed above, these judgments in no way advance the case of the respondents." From the aforesaid authorities, it is quite clear that DNA report deserves to be accepted unless it is absolutely dented and for non- acceptance of the same, it is to be established that there had been no quality control or quality assurance. If the sampling is proper and if there is no evidence as to tampering of samples, the DNA test report is to be accepted.

225. In order to establish a clear link between the accused persons and the incident at hand, the prosecution has also adduced scientific evidence in the form of DNA, fingerprint and bite mark analysis.

226. Various samples, for the purpose of DNA profiling, were lifted from the person of the prosecutrix; the informant; the accused, their clothes/ articles; the dumping spot; the iron rods; the ashes of partly burnt clothes; as well as from the offending bus. PW-45, Dr. B.K. Mohapatra, analysed the said DNA profiles and submitted his report thereof. In his report, he concluded that the samples were authentic and capable of establishing the identities of the persons concerned beyond reasonable doubt.

Guidelines and methodology documented in the Working Procedure Manuals of the laboratory which have been validated and recommended for use in the laboratory. He further added that once a DNA profile is generated, its accuracy is 100%. The trial court and the High Court have consistently noted that the counsel for the defence did not raise any substantial ground to challenge the DNA report during the cross-examination of PW-45. In such circumstances, there is no reason to declare the DNA report as inaccurate, especially when it clearly links the accused persons with the incident.

227. After establishing the identities of each of the accused persons, the informant and the prosecutrix through DNA analysis, **the DNA profiles** generated from the remaining samples, where the identity of biological material found thereon needed to be ascertained, were matched with the DNA profiles of the prosecutrix, the informant and the accused, generated earlier from known samples. Such an analysis cogently linked each of the accused with the victims as also with the crime scene. A summary of the findings in the report submitted by PW-45, Dr. B.K. Mohapatra, is as under:

"S.No.	Accused	DNA EVIDENCE
1	Ram Singh	Rectal swab from the prosecutrix contained DNA of male origin, which was found consistent with the DNA developed from the blood sample of this accused.
		DNA profile developed from the blood stains from the underwear, T-shirt and slippers of this accused was found consistent with the DNA of the prosecutrix.

"S.No.	Accused	DNA EVIDENCE
2	Mukesh	DNA profile developed from the blood stains from the pants, T-shirt and jacket of this accused was found consistent with the DNA of the prosecutrix.
3	Akshay	Breast swab of the prosecutrix contained DNA of male origin which was found consistent with the DNA of this accused.
		DNA profile developed from the blood stains from the jeans of this accused was found consistent with the DNA of the prosecutrix.
4	Vinay	DNA profile developed from the blood stains from the underwear, jacket and slippers of this accused was found consistent with the DNA of the prosecutrix.
5	Pawan	DNA profile developed from the blood stains from the sweater and shoes and slippers of this accused was found consistent with the DNA of the prosecutrix."

228. Further, a summary of the DNA analysis of the biological samples lifted from the material objects such as the bus, the iron rods, and the ash and unburnt pieces of clothes is also worth producing here:

"Serial No.	Identity of the victim	Findings of DNA Analysis
	Informant	The DNA profile developed from burnt clothes pieces was found to be of male origin and was consistent with the DNA profile of complainant.
		The bunch of DNA profile developed from hair and blood stained pieces of paper recovered from the bus was found consistent with the DNA profile of complainant.
		The DNA profile developed from blood stained dried leaves collected from the place where both the victims were thrown matched with the DNA profile of complainant.
	Prosecutrix	The DNA profile developed from blood stains from both the iron rods recovered at the instance of accused Ram Singh from the bus was of female origin and was consistent with the DNA profile of prosecutrix.
		The DNA profile developed from blood stains from curtains of the bus matched with the DNA profile of prosecutrix.
		The DNA profile developed from blood stains from seat covers was found consistent with the DNA profile of prosecutrix.
		DNA profile developed from blood stains from the bunch of the hair recovered from floor of the bus below sixth row seat, blood stains prepared from the roof of the bus near back gate, blood stains prepared from the floor of the bus near back gate, blood stains taken from side of back stairs of the bus, and blood stains taken from the inner side of the back door of the bus was found consistent with the DNA profile of prosecutrix.

230. Mr. Sharma, learned counsel appearing for appellants - Mukesh and Pawan Kumar Gupta, submitted that in the instant case, the DNA test cannot be treated to be accurate, for there was blood transfusion as the prosecutrix required blood and when there is mixing of blood, the DNA profiling is likely to differ. It is seemly to note, nothing had been put to the expert in his cross-examination in this regard. As the authorities relating to DNA would show, if the quality control is maintained, it is treated to be quite accurate and as the same has been established, we are compelled to repel the said submission of Mr. Sharma.

The evidence relating to finger print analysis:

231. Next aspect that is required to be adverted is the **evidence of fingerprint analysis** adduced by the prosecution to establish the identity of the accused persons. By virtue of the finger print analysis, the prosecution has tried mainly to establish the presence of the accused in the offending bus. On 17.12.2012 and 18.12.2012, a team of experts from the CFSL had lifted chance finger prints from the concerned bus, Ex.P-1, at Thyagraj Stadium. On 28.12.2012, PW-78, Inspector Anil Sharma of P.S. Vasant Vihar, the then S.H.O. of Police Station Vasant Vihar, requested the Director, CFSL for taking digital palm prints and foot prints of all the accused persons vide his letter Ex.PW-46/C. Pursuant to the said request made by PW-78, Inspector Anil Sharma, the CFSL on 31.12.2012 took the finger/palm prints and foot prints of the accused persons at Tihar Jail. After comparing the chance prints lifted from the bus with the finger prints/palm prints and foot prints of all the accused persons, PW-46, Shri A.D. Shah, Senior Scientific Officer (Finger Prints), CFSL, CBI, submitted his report, Ex.PW-46/D.

232. As per the report, Ex.PW-46/D, the result of the aforesaid examination of the Finger Print Division of the CFSL, CBI, New Delhi was that the chance prints of accused Vinay Sharma were found on the bus in question. The relevant portion of the report is as under:

"Result of Examination:

1. The chance print marked as Q.1 is identical with left palmprint specimen of Vinay Sharma S/o Sh. Hari Ram Sharma marked here as LPS-28 on the slip marked here as S.28 (Matching ridge characteristics have been found in their relative positions in the chance palmprint and specimen palm print. This forms the basis of the opinion that these prints are identical. Eight of them have been marked with projected red lines with their detailed description are placed at Annexure-1)

II. The chance print marked as Q.4 is identical with right thumb impression of Vinay Sharma S/o Sh. Hari Ram Sharma marked here as RTS-23 on the slip marked here as S.23 (Matching ridge characteristics have been found in their relative positions in the chance print and specimen finger print. This forms the basis of the opinion that these prints are identical. Eight of them have been marked with projected red lines with their detailed description are placed at Annexure-2)." The above report incontrovertibly proves that accused Vinay was present in the bus at the time of the incident. Be it noted, the other chance prints were found to be unfit for comparison or different from specimen print.

The comparison also shows that there is a concordance in terms of general alignment and angulation of the biting surfaces of the teeth of the lower jaw on the dental models of the accused person with the name Akshay and the corresponding bite marks visible on Photograph No.5. In particular, the comparison revealed concordance between the biting surface of the teeth on the lower jaw of the dental models of the accused person with the name Akshay and the bite mark visible on Photograph No.5 in relation to the rotated left first incisor whose mesial surface pointed towards the tongue.

Overall, the bite mark shows some degree of specificity to the accused person's teeth by virtue of a number of concordant points, including one corresponding unconventional/ individual characteristic. There is an absence of any unexplainable

discrepancies between the bite mark and the biting surfaces of this accused person's teeth. Therefore, the teeth on the dental models of the accused person with the name Akshay probably caused the bite marks visible on Photograph No.5."

239. Be it noted, the present is a case where the victim's body contained various white bite marks. Bite mark analysis play an important role in the criminal justice system. Advanced development of technology such as laser scanning, scanning electron microscopy or cone beam computed tomography in forensic odontology is utilised to identify more details in bite marks and in the individual teeth of the bite. Unlike fingerprints and DNA, bite marks lack the specificity and durability as the human teeth may change over time.

However, bite mark evidence has other advantages in the criminal justice system that links a specific individual to the crime or victim. For a bite mark analysis, it must contain abundant information and the tooth that made the mark must be quite distinctive.

240. Bite marks in the skin are photographed in cases where the suspect is apprehended. A thorough dental combination is administered after dental examination of the suspect. Final comparison of the details of the original mark with the dentation of the suspect is done by experts.

241. The bite marks generally include only a limited number of teeth. The teeth and oral structure of the accused are examined by experts and, thereafter, bite marks are compared and reports are submitted. Forensic Odontology is a science and the most common application of Forensic Odontology is for the purpose of identification of persons from their tooth structure.

242. Forensic Odontology has established itself as an important and indispensable science in medico-legal matters and expert evidence through various reports which have been utilized by courts in the administration of justice. In the case at hand, the report is wholly credible because of matching of bite marks with the tooth structure of the accused persons and there is no reason to view the same with any suspicion. Learned counsel for the appellants would only contend that the whole thing has been stage- managed. We are not impressed by the said submission, for the evidence brought on record cogently establish the injuries sustained by the prosecutrix and there is consistency between the injuries and the report. We are not inclined to accept the hypothesis that bite marks have been managed. Acceptability of the plea of alibi

"**Aggravating circumstances**: A court may, however, in the following cases impose the penalty of death in its discretion:

(a) if the murder has been committed after previous planning and involves extreme brutality; or

(b) if the murder involves exceptional depravity; or

(c) if the murder is of a member of any of the armed forces of the Union or of a member of any police force or of any public servant and was committed-

  (i) while such member or public servant was on duty; or

  (ii) in consequence of anything done or attempted to be done by such member or public servant in the lawful discharge of his duty as such member or public servant whether at the time of murder he was such member or public servant, as the case may be, or had ceased to be such member or public servant; or

(d) if the murder is of a person who had acted in the lawful discharge of his duty under Section 43 of the Code of Criminal Procedure, 1973, or who had rendered assistance to a Magistrate or a police officer demanding his aid or requiring his assistance under Section 37 and Section 129 of the said Code." After reproducing the same, the Court opined: "Stated broadly, there can be no objection to the acceptance of these indicators but as we have indicated already, we would prefer

not to fetter judicial discretion by attempting to make an exhaustive enumeration one way or the other."

333. Thereafter, the Court referred to the suggestions pertaining to mitigating circumstances: "Mitigating circumstances.-In the exercise of its discretion in the above cases, the court shall take into account the following circumstances:

(1) That the offence was committed under the influence of extreme mental or emotional disturbance.

(2) The age of the accused. If the accused is young or old, he shall not be sentenced to death.

(3) The probability that the accused would not commit criminal acts of violence as would constitute a continuing threat to society.

(4) The probability that the accused can be reformed and rehabilitated. The State shall by evidence prove that the accused does not satisfy the conditions (3) and (4) above.

(5) That in the facts and circumstances of the case the accused believed that he was morally justified in committing the offence.

(6) That the accused acted under the duress or domination of another person.

(7) That the condition of the accused showed that he was mentally defective and that the said defect impaired his capacity to appreciate the criminality of his conduct." The Court then observed: "We will do no more than to say that these are undoubtedly relevant circumstances and must be given great weight in the determination of sentence."

357. When we cautiously, consciously and anxiously weigh the aggravating circumstances and the mitigating factors, we are compelled to arrive at the singular conclusion that the aggravating circumstances outweigh the mitigating circumstances now brought on record. Therefore, we conclude and hold that the High Court has correctly confirmed the death penalty and we see no reason to differ with the same.

37.6 BENEFIT OF DOUBT[15]: (PROOF BEYOND REASONABLE DOUBT IS A GUIDELINE, NOT A FETISH.)

Author's Summary

About 90 % criminals committing heinous crime are given benefit of doubt and acquitted, making mockery of the criminal justice. Proof beyond reasonable doubt is a guideline, not a fetish. *A fair doubt is based upon reasons and common sense. It must grow out of the evidence.* The SC, in this case, has quoted chapter and verse from case law that exaggerated devotion to the rule of benefit of doubt must not nurture fanciful doubts or lingering suspicion and thereby destroy social defence.

It is a case of drug trafficking where the traffickers wanted to get the benefit of doubt. SC refused to accept the plea.

Relevant Extracts (verbatim)

The facts giving rise to the conviction and sentence of the appellants have been set out in detail by the High Court in the order under appeal hence need not be detailed

15. *Iqbal Moosa Patel v State of Gujarat*, AIR 2011 SC (Supp) 470.

over again except to the extent it is absolutely necessary to do so. Briefly stated the prosecution case is that a certain secret information was received by Mr. K.C. Chudasma, Inspector, Anti-Terrorist Squad which was passed on to Mr. P.S. Tomar, Zonal Director, Narcotics Control Bureau, Ahmedabad. The information suggested that Accused No. 2 Mr. Hemaram Chaudhary was the kingpin of a syndicate involved in smuggling and interstate trafficking of narcotic substances. Accused No. 3 Shri Derajram Jat was the man allegedly carrying out the operations at the instance of the said Mr. Hemaram Chaudhary. The information so received was used to intercept and search a truck bearing registration number RJ-04-G-1305 on 29th June, 2001 at Lal Bahadur Shastri Bridge, Pirana area in the city of Ahmedabad while the same was returning from Bharuch. The truck was driven by accused No. 4-Ashuram Durgaram Choudhary while accused No. 3 Derajram Jat was accompanying him. The search of the truck led to the seizure of psychotropic drugs from the aforesaid two persons who revealed that the consignment in question had been supplied by Mr. Hemaram Choudhary-accused No. 2.

On the basis of the information so collected and the disclosure made by the driver of the truck and Derajram Jat-accused No. 3. Appellant-Iqbal Moosa Patel was taken into custody and his statement under section 67 of the NDPS Act recorded. A raid was then carried out on 7th July, 2001 at village Varadia, Khadaki Street, District Bharuch, which led to the seizure of heroin weighing 3.056 kgs. and cash of Rs. 1,17,500 from the residence of appellant No. 1 Iqbal Moosa Patel. In his statement recorded under section 67 of the N.D.P.S. Act the said accused admitted having purchased four packets of brown sugar from one Master and Bhaikhanbhai both residents of Badmer in Rajasthan in the month of March, 2001, out of which one packet had already been sold to one Shakur while the remaining three were seized by the respondent from his residence as mentioned above.

On the basis of the material placed before the trial court the accused persons were charged with different offences to which the accused pleaded not guilty and claimed a trial.

13. That brings us to the question whether the appellants could be given the benefit of doubt having regard to the nature of the evidence adduced by the prosecution against them. We do not think that the appellants have made out a case for grant of any such benefit.

It is true that the prosecution is required to establish its case beyond a reasonable doubt, but that does not mean that the degree of proof must be beyond a shadow of doubt. The principle as to what degree of proof is required is stated by Lord Denning in his inimitable style in *Miller* v *Minister of Pensions*, (1947) 2 All ER 272 : 177 LT 536 : 63 TLR 474:

> *"That degree is well-settled. It need not reach certainty, but it must carry a high degree of probability. Proof beyond reasonable doubt does not mean proof beyond a shadow of a doubt. The law would fail to protect the community if it permitted fanciful possibilities to deflect the course of justice. If the evidence is so strong against a man as to leave only a remote possibility in his favour which can be dismissed with sentence of course, it is possible but not in the least probable,' the case is proved beyond reasonable doubt....*

It is true that under our existing jurisprudence in a criminal matter, we have to proceed with presumption of innocence, but at the same time, that presumption is to be judged on the basis of conceptions of a reasonable prudent man. Smelling doubts for the sake of giving benefit of doubt is not the law of the land."

14. *Reference may also be made to the decision of this Court in Sucha Singh v State of Punjab,* (2003) 7 SCC 64 : AIR 2003 SC 3617 : 2003 AIR SCW 3984*, where this Court has reiterated the principle in the following words:*

"…… ***Exaggerated devotion to the rule of benefit of doubt must not nurture fanciful doubts or lingering suspicion and thereby destroy the social defence. Justice cannot be made sterile on the plea that it is better to let a hundred guilty escape than punish an innocent letting the guilty escape is not doing justice according to law.*** *[See Gurbachan Singh v Satpal Singh,* AIR 1990 SC 209 : 1990 Cr LJ 562 : JT 1989 (4) SC 38].

Prosecution is not required to meet any and every hypothesis put forward by the accused. A reasonable doubt is not an imaginary, trivial or merely possible doubt, but a fair doubt based upon reason and common sense. It must grow out of the evidence in the case. If a case is proved perfectly, it is argued that it is artificial; if a case has some flaws inevitable because human beings are prone to err, it is argued that it is too imperfect. One wonders whether in the meticulous hypersensitivity to eliminate a rare innocent from being punished, many guilty persons must be allowed to escape.

Proof beyond reasonable doubt is a guideline, not a fetish."

37.7 PROOF 'BEYOND REASONABLE DOUBT'[16]: (USE/MISUSE)

Author's Note

This is a landmark judgment of SC on frequent acquittals. In more than 90% heinous crimes, the criminals are acquitted on the single plea: not proved *'beyond reasonable doubt'*, by doubting Thomases, mostly on unsound grounds; making mockery of Criminal Justice System and promoting lawlessness in the country.

The Apex court has condemned the misuse of the phrase ***'not proved beyond reasonable doubt".***

Highlights italicised

Relevant Extracts (Verbatim)

Even at this stage we may remind ourselves of a necessary social perspective in criminal cases which suffers from sufficient forensic appreciation.

The dangers of exaggerated devotion to the rule of benefit of doubt at the expense of social defence and to the soothing sentiment that all acquittals are always good regardless of justice to the victim and the community, demand especial emphasis in the contemporary context of escalating crime and escape. The judicial instrument has a public accountability. The cherished principles or golden thread of proof beyond reasonable doubt which runs through the web of our law should not be stretched morbidly to embrace every punch, hesitancy and degree of doubt. The excessive solicitude reflected in the attitude that a thousand guilty men may go but one innocent martyr shall not suffer is a false dilemma.

Only reasonable doubts belong to the accused. Otherwise any practical system of justice will then break down and lose credibility with the community. The evil of acquitting a guilty person light-heartedly as a learned author has sapiently observed, goes much beyond the simple fact that just one guilty person has gone unpunished. If unmerited acquittal become general, they tend to lead to a cynical disregard of the law, and this in turn leads to a public demand for harsher legal presumptions against indicted 'persons' and more severe punishment of those who are found guilty. Thus, too frequent acquittals of the guilty may lead to a ferocious penal law, eventually eroding the judicial protection of the guiltless. For all these reasons it is true to say, with Viscount Simon, that

"a miscarriage of justice may arise from acquittal of the guilty no less than from the conviction of the innocent……"

16. *Shivaji Sahebrao Bobade v State of Maharashtra,* AIR 1973 SC 2622 : (1973) 2 SCC 793 : 1973 Cr L J 1783.

37.8 CIRCUMSTANTIAL EVIDENCE[17]

Author's Summary

It is a case of murder. The culprit brought a female with him to Delhi, stayed in a hotel, killed her and left the body in the hotel and vanished from the scene. There were no eyewitnesses to his heinous crime at Delhi. He was convicted on circumstantial evidence. SC maintained the conviction, It did not accept the defence objection to such conviction. SC also laid the law, with support from other similar cases:

1. **"the Courts will be well-advised in case of circumstantial evidence to be watchful and to ensure that conjectures and suspicions do not take place of legal proof.**
2. **"it is well-settled that those circumstances must be proved to be such as to be conclusive of the guilt of the accused and incapable of explanation on any hypothesis consistent with the innocence of the accused.**
3. **"Modern thinking is in favour of the view that proof beyond a reasonable doubt is the same as proof which affords moral certainty to the Judge."**

Highlights italicised

Relevant Extracts (Verbatim)

> The learned Senior Advocate, Mr. Jaspal Singh, has been able to state the proposition of law with due clarity. It has been contended that in the event of there being only circumstantial evidence, it is well-settled that those circumstances must be proved to be such as to be conclusive of the guilt of the accused and incapable of explanation on any hypothesis consistent with the innocence of the accused. It has been contended further that it is on this score the law seems to be well-settled as well, to writ that the Courts will be well-advised in case of circumstantial evidence to be watchful and to censure that conjectures and suspicions do not take place of legal proof. It has been the appellant's contention that the prosecution has utterly failed to link up the chain and as a matter of fact the snap in the chain is not very far to seek, thus warranting an order of acquittal and the High Court has fallen into a manifest error in regard thereto. The evidence of PW-1 and PW-23 being Madan Singh and Dinesh Chand was taken recourse to. It is on this score, it has been contended that (a) None of them has identified the appellant; (b) None of them has stated the it was the appellant who had checked in on 18-9-1991; (c) None of them has stated that it was the appellant who had checked out on 19-9-1991 at 8.30 a.m.; and (d) Rather both the witnesses have stated that appellant was not the person who had checked in on 18-9-1991 or who had checked-out in on 18-9-1991 at 8.30 a.m. and drawing inspiration therefrom, Mr. Singh in support of the appeal contended that there is thus no direct evidence available to prove that it was the appellant who had checked in on 18th September, 1991 or had left the hotel on 19th September, 1991. Admittedly, there is no difficulty in appreciating the submissions of Mr. Singh. Availability of direct evidence is not there but what about the circumstances? Before doing so, be it noted that the evidence of PW-6, Sahmim Bano as to the date of departure of the accused with his wife Hazra *alias* Halima from Bombay to Delhi and the subsequent telephonic message that Halima died in a bus accident and that cremation has taken place in Nizamuddin stand out to be a rather significant component of the chain of evidence.

17. *State of Madhya Pradesh v Sanjay Rai,* AIR 2004 SC 2174 : 2004 AIR SCW 1919 : 2004 Cr LJ 2006 (SC). May also see: *Golam Majibuddin v State of West Bengal*, 1972 Cr LJ 1342 (SC); *Mahmood v State of Uttar Pradesh*, AIR 1976 SC 69 : (1976) 1 SCC 542 : 1976 Cr LJ 10; *Sanwat Singh v State of Rajasthan*, AIR 1961 SC 715 : (1961) 3 SCR 126 : (1961) 1 Cr LJ 766.

(a) The appellant came to visit Delhi along with his wife Hazra *alias* Halima leaving Bombay on 17th September, 1991.

(b) On 18th September, 1991 at about 8.50 p.m. both of them claimed to be husband and wife. Alamgir, appellant entered his name and address in the guest register and received the key of Room No. 107 and stayed in Room No. 107 in Royal Inn Guest House, Netaji Subhash Marg, Daryaganj, Delhi.

(c) On 19th September, 1991 in the morning at 8.30 a.m., Alamgir left the guest house locking his wife in the room and did not return thereafter.

(d) The appellant telephonically informed PW-6, Shamim Bano that the deceased died in a bus accident and was buried in Nizamuddin and thereafter the appellant left Delhi for Bombay.

(e) The appellant's wife was found dead due to strangulation in Room No. 107 on opening of the same with a duplicate key on 20th September, 1991.

(f) The appellant was arrested at Bombay on 21st September, 1991 and key of the room was recovered from him along with ticket from Delhi to Bombay dated 19th September, 1991 proving that he after killing his wife instead of taking her care, had left for Bombay on 19th September, 1991. Only beyond the range of a reasonable doubt, of course, the expression 'reasonable doubt' is incapable of definition. Modern thinking is in favour of the view that proof beyond a reasonable doubt is the same as proof which affords moral certainty to the judge.

The question for consideration is thus as to whether the circumstances noticed above would form a complete chain of events without any snap and pointedly point to the accused as the guilty person and to no-one else. In the event there is an answer in the affirmative, question of interference with the order of the High Court would not arise. Incidentally, the High Court did emphasize on the true and correct meaning of the phraseology 'reasonable doubt' to be attributed thereon and it is on this score, the High Court records:

Modern thinking is in favour of the view that proof beyond a reasonable doubt is the same as proof which affords moral certainty to the Judge.

We are, however, not expressing any opinion with regard thereto. Suffice it to say that sufficiency of moral certainty itself is a matter for deliberation and since the matter has not been addressed to us on that score, expression of opinion on the same would not arise.

The circumstances noticed above, if read with the evidence of PW-6, Shamim Bano as to the date of departure of the accused with his wife Hazra *alias* Halima from Bombay to Delhi and the telephonic message after two days that Halima had died in a bus accident and that she had been cremated at a cremation ground in Nizamuddin – this piece of evidence, as noticed above, if read along with the circumstances noticed above, would form a chain without there being any snap. Strenuous submissions have been made as regards the admissibility of the Handwriting Expert's opinion as also a challenge thrown to the non-admissibility of the entire evidence of Shamim Bano, PW-6. This evidence of Shamim Bano has been challenged on two counts: on the first Shamim Bano, being the sister of Halima, was an interested witness and secondly, she did not say so in a statement before the police under section 161, Cr. P.C. Interested witness by itself cannot possibly be a ground to reject the evidence on record. The test of creditworthiness or acceptability, in our view, ought to be the guiding factor and if so, question of raising an eyebrow on the reliability of witness being an interested witness would be futile in the event of the evidence being otherwise acceptable, there ought not to be any hindrance in the matter of prosecutor's success. The evidence must inspire confidence and in the event of unshaken credibility, there is no justifiable reason to reject the same. It is on this score the issue of interested witness thus stands negated, as raised by the appellant. The second limb pertains to the statement under section 161, Cr. P.C. Admittedly, the piece of evidence was not available in the statement of the witness under section 161, Cr. P.C., but does it take away the nature and character of the evidence in the event there is some omission on the part of the police official. Would that be taken recourse to as amounting to a rejection of an

otherwise creditworthy and acceptable evidence—the answer, in our view, cannot but be in the negative. In that view of the matter, the evidence of PW-6 thus ought to be treated as creditworthy and acceptable and it is to be seen as the effect of such an acceptability.

Similar, however, is the opinion of this Court in *Pawan Kumar v State of Haryana*, (2001) 3 SCC 628 : AIR 2001 SC 1324 : 2001 AIR SCW 1111, in which one of us (U.C. Banerjee, J.) was a party. The opinion of the Court runs as under:

> Incidentally, success of the prosecution on the basis of circumstantial evidence will, however, depend on the availability of a complete chain of events so as not to leave any doubt for the conclusion that the act must have been done by the accused person. While, however, it is true that there should be no missing links, in the chain of events so far as the prosecution is concerned, but it is not that every one of the links must appear on the surface of the evidence, since some of these links may only be inferred from the proven facts. Circumstances of strong suspicion without, however, any conclusive evidence are not sufficient to justify the conviction and it is on this score that great care must be taken in evaluating the circumstantial evidence. In any event, on the availability of two inferences, the one in favour of the accused must be accepted and the law is well-settled on this score, as such we need not dilate much in that regard excepting, however, noting the observations of this Court in the case of *State of Uttar Pradesh v Ashok Kumar Srivastava*, AIR 1992 SC 840 : 1992 AIR SCW 640 : 1992 Cr LJ 1104, wherein this Court in paragraph 9 of the report observed:—
>
> *"This Court has, time out of number, observed that while appreciating circumstantial evidence the Court must adopt a very cautious approach and should record a conviction only if all the links in the chain are complete pointing to the guilt of the accused and every hypothesis of innocence is capable of being negatived on evidence. Great care must be taken in evaluating circumstantial evidence and if the evidence relied on is reasonably capable of two inferences, the one in favour of the accused must be accepted. The circumstance relied upon must be found to have been fully established and the cumulative effect of all the facts so established must be consistent only with the hypothesis of guilt. But this is not to say that the prosecution must meet any and every hypothesis put forward by the accused, however, far-fetched and fanciful it might be. Nor does it mean that prosecution evidence must be rejected on the slightest doubt because the law permits rejection if the doubt is reasonable and not otherwise."*
>
> The other aspect of the issue is that the evidence on record, ascribed to be circumstantial, ought to justify the inferences of the guilt from the incriminating facts and circumstances which are incompatible with the innocence of the accused or guilt of any other person. The observations of this Court in the case of *Balwinder Singh v State of Punjab*, AIR 1987 SC 350 : 1987 Cr LJ 330 : (1987) 1 SCC 1 lends concurrence to the above."

In a more recent decision of this Court in *Sudama Pandey v State of Bihar*, (2002) 1 SCC 679, the law as noticed above and to the same effect stands very felicitously expressed.

There is no doubt that conviction can be based solely on circumstantial evidence but it should be tested by the touch-stone of law relating to circumstantial evidence laid down by this Court as far back as in 1952.

In *Hanumant Govind Nargundkar v State of Madhya Pradesh*, AIR 1952 SC 343 : 1952 SCJ 509 : 1952 SCR 1091, it was observed thus:

> *It is well to remember that in cases where the evidence is of a circumstantial nature, the circumstances from which the conclusion of guilt is to be drawn should in the first instance be fully established and all the facts so established should be consistent only with the hypothesis of the guilt of the accused. Again, the circumstances should be of a conclusive nature and tendency and they should be such as to exclude every hypothesis but the one proposed to be proved. In other words, there must be a chain of evidence so far complete as not to leave any reasonable ground for a conclusion consistent with the innocence of the accused and it must be such as to show that within all human probability the act must have been done by the accused.*

A reference may be made to a later decision in *Sharad Birdhichand Sarda v State of Maharashtra*, AIR 1984 SC 1622 : (1984) 4 SCC 116 : 1984 Cr LJ 1738. Therein, while dealing with circumstantial evidence, it has been held that onus was on the prosecution to prove that the chain is complete and the infirmity of lacuna in prosecution cannot be cured by false defence or plea.

The conditions precedent in the words of this Court, before conviction could be based on circumstantial evidence, must be fully established. They are:

(1) the circumstances from which the conclusion of guilt is to be drawn should be fully established. The circumstances concerned 'must' or 'should' and not 'may be' established;

(2) the facts so established should be consistent only with the hypothesis of the guilt of the accused, that is to say, they should not be explainable on any other hypothesis except that the accused is guilty;

(3) the circumstances should be of a conclusive nature and tendency;

(4) they should exclude every possible hypothesis except the one to be proved; and

(5) there must be a chain of evidence so complete as not to leave any reasonable ground for the conclusion consistent with the innocence of the accused and must show that in all human probability the act must have been done by the accused.

These aspects were recently highlighted in *State of Rajasthan v Rajaram*, AIR 2003 SC 3601 : 2003 AIR SCW 4097 : 2003 Cr LJ 3901.

There is no doubt that conviction can be based solely on circumstantial evidence but it should be tested by the touchstone of law relating to circumstantial evidence laid down by this Court as far back as in 1952.

37.9 "RAREST OR RARE CASE"[18]

Author's Summary

It is a landmark judgment in which the Apex Court discussed the Case Law on the subject. It provides guidelines to identify the 'Rarest of the Rare Cases' and also discussed the situations how to differentiate them from the borderline murder cases.

In this case, a husband-wife pair killed close relatives for pelf. The Trial Court sentenced them to death. High Court changed the sentence to life imprisonment. SC found the case to be Rarest of the rare cases and sentenced them to death.

Highlights italicised

Relevant Extracts (verbatim)

Having held that both A-1 and A-2 are guilty of the murder of deceased Relu Ram and his family and that their conviction under section 302 read with section 34 and section 120B and other provisions inflicted upon them by both the courts below does not call for any interference by this Court,

> *we now proceed to decide whether the instant case is one of rarest of rare cases warranting death sentence, as has been held by the trial court to be one, or the one in which sentence of life imprisonment would be appropriate, as has been held by the High Court while commuting the sentence of death to life imprisonment.*

Learned counsel appearing on behalf of the accused submitted that the present case cannot be said to be rarest of the rare one so as to justify the imposition of extreme penalty of death.

18. *Ram Singh v Sonia*, AIR 2007 SC 1218 : 2007 AIR SCW 1278 : 2007 Cr LJ 1642.

This question has been examined by this Court times without number. In the case of *Bachan Singh v State of Punjab,* (1980) 2 SCC 684 : AIR 1980 SC 898 : 1980 Cr LJ 636 before a Constitution Bench of this Court validity of the provision for death penalty was challenged on the ground that the same was violative of articles 19 and 21 of the Constitution and while repelling the contention, the Court laid down the scope of exercise of power to award death sentence and the meaning of the expression "rarest of the rare" so as to justify extreme penalty of death and considered that clauses (1) and (2) of Article 6 of the International Covenant on Civil and Political Rights to which India has acceded in 1979 do not abolish or prohibit the imposition of death penalty in all circumstances. All that they required is that, *firstly*, death penalty shall not be arbitrarily inflicted; *secondly*, it shall be imposed only for most serious crimes in accordance with a law, which shall not be an *ex post facto* legislation. The Penal Code prescribes death penalty as an alternative punishment only for heinous crimes, which are not more than seven in number. Section 354(3) of the Criminal Procedure Code, 1973 in keeping with the spirit of the International Covenant, has further restricted the area of death penalty. Now according to this changed legislative policy, which is patent on the face of section 354(3), the normal punishment for murder and six other capital offences under the Penal Code, is imprisonment for life (or imprisonment for a term of years) and death penalty is an exception. The present legislative policy discernible from section 235(2) read with section 354(3) is that in fixing the degree of punishment or making the choice of sentence for various offences, including one under section 302, Penal Code, the Court should not confine its consideration "principally" or merely to the circumstances connected with the particular crime, but also give due consideration to the circumstances of the criminal. In many cases, the extremely cruel or beastly manner of the commission of murder is itself a demonstrated index of the depraved character of the perpetrator. And it is only when the culpability assumes the proportion of extreme depravity that "special reasons" can legitimately be said to exist. Judges should never be bloodthirsty. It is, therefore, imperative to voice the concern that courts, aided by the broad illustrative guidelines indicated, will discharge the onerous function with evermore scrupulous care and humane concern, directed along the highroad of legislative policy outlined in section 354(3), *viz.*, that for persons convicted of murder, life imprisonment is the rule and death sentence an exception.

In the case of *Machhi Singh v State of Punjab,* AIR 1983 SC 957 : 1983 Cr LJ 1457 : (1983) 3 SCC 470, a 3-Judge Bench of this Court following the decision in *Bachan Singh* (supra), observed

> *that in rarest of rare cases when collective conscience of the community is so shocked that it will expect the holders of the judicial power centre to inflict death penalty irrespective of their personal opinion as regards desirability or otherwise of retaining death penalty. The community may entertain such a sentiment in the following circumstances:*
>
> *I.* ***When the murder is committed in an extremely brutal, grotesque, diabolical, revolting or dastardly manner so as to arouse intense and extreme indignation of the community. For instance,***
>
> *(i) when the house of the victim is set aflame with the end in view to roast him alive in the house;*
>
> *(ii) when the victim is subjected to inhuman acts of torture or cruelty in order to bring about his or her death; and*
>
> *(iii) when the body of the victim is cut into pieces or his body is dismembered in a fiendish manner.*
>
> *II.* ***When the murder is committed for a motive which, evinces total depravity and meanness. For instance when***
>
> *(a) hired assassin commits murder for the sake of money or reward; or*
>
> *(b) a cold-blooded murder is committed with a deliberate design in order to inherit property or to gain control over property of a ward or a person under the control of the murderer or vis-a-vis whom the murdered is in a dominating position or in a position of trust; or*
>
> *(c) a murder is committed in the course for betrayal of the motherland.*

III.

(a) When the murder of a member of a Scheduled Caste or minority community etc., is committed not for personal reasons but in circumstances etc., which arouse social wrath. For instance when such a crime is committed in order to terrorise such persons and frighten them into fleeing from a place or in order to deprive them of, or make them surrender, lands or benefits conferred on them with a view to reverse past injustices and in order to restore the social balance.

(b) In cases of 'bride burning" and what are known as 'dowry deaths' or when murder is committed in order to remarry for the sake of extracting dowry once again or to marry another woman on account of infatuation.

IV. When the crime is enormous in proportion. For instance, when multiple murders say of all or almost all the members of a family or a large number of persons of a particular caste, community, or locality, are committed.

V. When the victim of murder is

(a) an innocent child who could not have or has not provided even an excuse, much less a provocation, for murder;

(b) a helpless woman or a person rendered helpless by old age or infirmity;

(c) when the victim is a person vis-a-vis whom the murderer is in a position of domination or trust;

(d) when the victim is a public figure generally loved and respected by the community for the services rendered by him and the murder is committed for political or similar reasons other than personal reasons.

In the said case, the Court further observed that in this background the guidelines indicated in the case of *Bachan Singh* (supra) will have to be culled out and applied to the facts of each individual case and where the question of imposing death sentence arises, the following proposition emerge from the case of *Bachan Singh* (supra):—

(i) The extreme penalty of death need not be inflicted except in gravest cases of extreme culpability.

(ii) Before opting for the death penalty the circumstances of the 'offender' also require to be taken into consideration along with the circumstances of the 'crime'.

(iii) Life imprisonment is the rule and death sentence is an exception. In other words death sentence must be imposed only when life imprisonment appears to be an altogether inadequate punishment having regard to the relevant circumstances of the crime, and provided, and only provided, the option to impose sentence of imprisonment for life cannot be conscientiously exercised having regard to the nature and circumstances of the crime and all the relevant circumstances.

(iv) A balance-sheet of aggravating and mitigating circumstances has to be drawn up and in doing so the mitigating circumstances have to be accorded full weightage and a just balance has to be struck between the aggravating and the mitigating circumstances before the option is exercised.

The Court thereafter observed that in order to apply these guidelines the following questions may be answered:—

(a) Is there something uncommon about the crime, which renders sentence of imprisonment for life inadequate and calls for a death sentence?

(b) Are the circumstances of the crime such that there is no alternative but to impose death sentence even after according maximum weightage to the mitigating circumstances which speak in favour of the offender?

Ultimately, in the said case of *Machhi Singh* (supra), the Court observed that if upon an overall global view of all the circumstances in the light of the aforesaid proposition and taking into account the answers to the questions posed hereinabove, the circumstances of the case are such that death sentence is warranted, the Court would proceed to do so.

In the light of the law already laid down by this Court referred to above, now this Court is called upon to consider whether the present case would come within the realm of the rarest of the rare or not.

The instant case is one wherein accused Sonia, along with accused Sanjiv [her husband] has not only put an end to the lives of her step-brother and his whole family, which included three tiny tots of 45 days, 2-1/2 years and 4 years, but also her own father, mother and sister in a very diabolic manner so as to deprive her father from giving the property to her step-brother and his family. The fact that murders in question were committed in such a diabolic manner while the victims were sleeping, without any provocation whatsoever from the victims' side indicates the cold-blooded and premeditated approach of the accused to cause the death of the victims. The brutality of the act is amplified by the grotesque and revolting manner in which the helpless victims have been murdered which is indicative of the fact that the act was diabolic of most superlative degree in conception and cruel in execution and that both the accused persons are not possessed of the basic humanness and completely lack the psyche or mind set which can be amenable for any reformation. If this act is not revolting or dastardly, it is beyond comprehension as to what other act can be so.

In view of these facts we are of the view that there would be a failure of justice in case death sentence is not awarded in the present case as the same undoubtedly falls within the category of rarest of rare cases and the High Court was not justified in commuting death sentence into life imprisonment. In the result Criminal Appeal No. 142 of 2006 filed by the accused persons is dismissed whereas Criminal Appeal No. 895 of 2005 filed by private prosecutor and Criminal Appeal No. 894 of 2005 filed by the State of Haryana are allowed, order passed by the High Court commuting death sentence into life imprisonment is set aside and order of the trial court awarding death sentence is restored.

37.10 FINGERPRINTS: IDENTIFICATION BASIS[19]

Author's Summary

This is an important case. It discusses the number of matching points to declare identification of a fingerprint. Various counties/bureaus use different numbers, usually from 6 to 16.The court has accepted that**: *'if there are five or six 'well-grouped' characteristics and the patterns uncommon, the identification is definite'. The consensus of modern opinion is that six, four in sequence, are sufficient to justify a definite opinion being given."***

Highlights italicised

Relevant Extracts (verbatim)

Interest in modern fingerprints identification dates from 1880. With the publication of articles of Henry-Faulds and W.J. Herschel, who was in Indian Civil Service, about uniqueness and permanence of fingerprints, facts which the English Scientist Sir R. Galton was to verify through lengthy systematic observations. Systems of fingerprint classification were developed later by Sir E.R. Henry, formerly of Indian Civil Service and afterwards Chief Commissioner of the London Metropolitan Police and by Juan Vucetich of Argentina. However, Henry system of classification has been adopted by scores of law enforcement agencies around the world and is the most widely used method of fingerprint classification. All impressions are broadly classified as arches, loops, whorls and composites or compounds and there are further sub-divisions. In arches the ridges run from one side to the other without making a backward turn, unlike to loops, whorls or composites. In loop, whorl or composites types there are fixed points, which are known as delta or

19. *State of Madhya Pradesh v Sitaram Rajput*, 1978 Cr LJ 1220 : 1978 MPLJ 197.

outer terminus and the core or the inner terminus. These serve a useful purpose in the classification of fingerprints. Generally there are no deltas or cores in arches. There are also considerable amount of finger details of branching and coalescence of ridges, of island and unlimited quantity of extremely fine pore details along individual ridges. About 5 per cent of the impressions are arches, 60 per cent loops and 35 per cent whorls and composites. Loops and whorls always predominate.

For the purpose of comparison of two fingerprints, *i.e.,* the disputed and the specimen, to begin with the patterns are seen. If the patterns are different then the impressions are of different persons. If the patterns are similar then it is seen whether general flow of the ridges is similar. Then the ridge characteristics of the two impressions are compared. Two common fixed points are then located. In cases of loops, whorls or composites, core is taken as the inner terminus and the delta outer terminus. Generally speaking, core and delta are not available in cases of arches. So also in partial or blurred impressions such core and delta may not be available. So dot, rod, ridge end, bifurcation, island etc., are taken as the starting point. Similarly outer point is fixed. Having got or fixed the two points, their similarity is determined by counting the number of ridges in between the two points. If the numbers tally, then the sequence of individual ridge characteristics and their relative positions are observed. The points of similarities are then noted. If the relation of each of the points so noted in both the impressions is the same it is an absolute certainty that the impressions are of the same person.

Now question remains as to how many points of similarities can definitely establish the identity beyond question. The Federal Bureau of Investigation of USA requires twelve and the Scotland yards requires sixteen points of similarities for positive identification. However, some English and American authorities are of the view that if there are five or six 'well-grouped' characteristics and the patterns uncommon, the identification is definite. By well-grouped characteristics, they mean dots, islands, books and spurs. If five or six characteristics occur close to one another and in a narrow area, the force of identity is enhanced. In the case of blurred or partial impressions, the view of some of the Indian authors is that if there are three identical points, they would be sufficient to prove the identity. This has been questioned by other Indian authors who insist on at least six points of similarities to establish the identity. The Finger Prints Bureau of different States in India have fixed varying standards, requiring six to twelve points of similarities to determine the identity. In para 88 of the Finger Print Manual of M.P. State it has been observed: "If a sufficient number of ridge characteristics are in complete agreement in the two impressions it can be said definitely that the impressions were made by the same person. However, no definite rule can be laid down for fixing the number of the points of similarities. Four or five might be sufficient if there were unusual peculiarities. The consensus of modern opinion is that six, four in sequence, are sufficient to justify a definite opinion being given." It is said that the number is now changed to eight in Madhya Pradesh in view of certain decision of this court. The following extracts from the book Modern Criminal Investigation by Soderman and O'Connell may be quoted here in this regard:—

> *"The demand for twelve similar details is the result of the opinion of bygone days, founded on the opinion of Galton, Remus, Balthazard and others. All recent scientists working in the field of dactyloscopy, as for instance, Locard, De Rechter and others, share the opinion that the number of characteristic points which can be noted at the edge of an enlargement is a matter of little importance. A rare detail is an identification sign one hundred times more important than a whole series of forks, four to five details in a centre of an unusual pattern have much more value as evidence than twelve to fifteen forks in the periphery. Some ridges with unusually grouped pores have more weight than the classical twelve points".*

The branch of fingerprint is now a highly developed and technical subject. The classification of fingerprints is a science requiring much study and specialisation in the subject. Therefore, a fingerprint expert is in a more advantageous position to compare fingerprints and point out similarities or dissimilarities between two impressions by critical examination of the impressions. This was recognised by amendment of section 45 of the Evidence Act in 1899, making opinion of fingerprint expert relevant as was

the case with medical and hand-writing experts. Section 73 of the Act was also suitably amended, enabling taking of specimen thumb impressions for comparison. Section 510 of the Code of Criminal Procedure was amended in 1955 to make the report of the Director of Finger Print Bureau admissible under that section. The Supreme Court in *Phool Kumar v Delhi Administration,* AIR 1975 SC 905 : 1975 Cr LJ 778 : (1975) 1 SCC 797 has held that when neither the court nor the prosecution or the accused filed any application to summon and examine the fingerprint expert as to the subject-matter of his report, no objection can be taken at the appellate stage by the accused against his non-examination.

Majority of the High Courts have found that it cannot be laid down as a rule of law that it is unsafe to have conviction on the uncorroborated testimony of a fingerprint expert. The true rule seems to be one of caution. The court cannot delegate its authority to the expert but has to satisfy itself as to the value to be given to the evidence of the expert in the same way as to the value given to any other evidence. The reasons given by the expert in arriving at the conclusion are ultimately to be weighed by the court and satisfy itself about the correctness of the conclusion by comparison of the prints. The task of the court becomes much easier when the fingerprint expert has taken enlarged photo prints of the disputed and specimen fingerprints and marked the distinct points of similarities. Otherwise it becomes an uphill task to examine each and every individual prints with magnifying glass when there are large number of prints. If the enlarged photo prints are kept side by side and their marking compared, it becomes much easier to follow the reasonings of the fingerprint expert about points of similarities or dissimilarities and judge the correctness of his conclusion. In *Emperor v Sahdeo,* (1907) 3 Nag LR 1 : 5 Cr LJ 220 it has been observed:

> *"The papillary ridges covering the bulbous points of the human finger and thumb with which finger impressions are produced afford a surer criterion of identity than any other comparable body feature.*
>
> ***Where it is proved by competent expert testimony that two such impressions, made at different times, however far apart, contain several points of agreement and no points of disagreement in their minutial, no further evidence is necessary to prove that they were made by the same finger."***

There are no eyewitnesses in the case and obviously there could be none when the disbursing officer, officer certifying the works, muster-roll clerks and mates who had put their thumb-impression the muster-rolls against the fictitious names of various labourers are all accused persons. As the names of the labourers mentioned in the muster-rolls are all fictitious and to avoid detection the names of their villages were not mentioned and so there was no question of examining any of the labourers to show that they were never paid the wages as shown in the muster-roll. The prosecution case can only succeed if the prosecution is able to prove beyond doubt that the thumb impressions on the muster-rolls are all forged and they are, in fact, the thumb-impressions of the various respondents. The prosecution case, therefore, hinges on the evidence of fingerprint experts. We have the report, Ex. P. 143, of the Director of Finger Print Bureau which is admissible in evidence under section 510 of the Code although he has not been examined as a witness. We have also the report, Ex. P. 142 of Shri Vinayak (P.W. 53) who has been examined in court. The learned judge found the evidence of the fingerprint expert to be not satisfactory and he has given cogent reasons for arriving at this conclusion. It cannot be said that the reasoning of the learned judge is either perverse or unreasonable. In an appeal against acquittal it is not open to interfere even if another view of the evidence is reasonably possible, but here we are satisfied that the reasonings are well merited and there is nothing to differ from the view taken. There were in all about 320 disputed thumb-impressions which were alleged to be those of respondents Harisingh, Dalu, Khumansingh, Makhansingh and Maharajsingh and were referred to the fingerprint experts. The experts found that out of these 320 impressions some are smudged and are not fit for comparison, still the experts were left with quite a large number of legible fingerprints and it was not at all difficult to conclusively prove that the disputed fingerprints tally with the fingerprints of the aforesaid respondents. The fingerprint expert Vinayak,

(P.W. 53) had taken photo enlargement of only 12 disputed prints. He has also given his reasonings only in respect of these 12 prints though he stated that he had examined the other legible disputed prints with the specimen and he found them to be similar by examining the other prints which were not enlarged by magnifying glass. It may be mentioned that the reports Ex. P. 142 of Shri Vinayak and Ex. P. 143 of the Director do not tally in all respects. In Ex. P. 142 of Shri Vinayak questioned prints 442, 446, 465, 468A, 468C and 468D are shown as identical but the Director has stated in the report that these prints are unfit for comparison. Questioned prints 550, 554, and 554A have been stated by the expert to be identical but there is no such report about them by Director. Similar is the case with regard to prints 606 and 606A. If there are points of similarities between disputed and specimen prints there is no reason why the expert should differ.

Shri Vinayak admits that the best course to follow is to prepare enlarged photographs of the disputed and specimen prints to the same scale. Then, on the photographs a line may be drawn to connect the centre and the junction points. The lines between the two points should now be carefully counted. The next step is to find out how many agreements in detail there are on either side of the drawn line, such as free ends, forks, ellipses, tongues and rods and to see how they are situated as regards their relative positions with one another. One should also verify that the general pattern is the same in both, but he clearly admits that he did not consider the pattern of the prints. He has failed to take enlarged photographs of all the disputed prints which were subject to examination and comparison by him. He has not marked two fixed points nor drawn a line between the two points, nor he has counted the number of ridges in between. Although he admits that most of the disputed fingerprints were quite legible, still he has only marked out six points of similarities in each of 12 enlargements of the disputed fingerprints. His opinion is mainly based on the ridge characteristics which agree in nature and relative position. Perhaps, he has followed the instructions in the Finger Print Manual of M.P. State but in the Manual it is mentioned that 4 or 5 points of similarities might be sufficient if there are unusual peculiarities. Though normally six points of similarities, four in sequence, are sufficient to justify a definite opinion being given. It is not the opinion of Shri Vinayak that any of these prints had unusual peculiarities nor he has stated that at least four points of similarities were in sequence. This apart he has contradicted his report in the cross-examination in respect of several items. About photo enlargement, Ex. P. 126, he has mentioned that to the east of point No. 3 there is west-ward bifurcation with no ridge intervening but in cross-examination he admitted that point No. 4 is an end of a ridge. Similarly with regard to photo enlargement, Ex. P. 128 he has mentioned that point No. 1 is end of a ridge and to the east of point No. 3 and after the intervention of 3 ridges there is end of a ridge but in cross-examination he admitted that point No. 1 is an upward bifurcation and is not end of a ridge and point No. 4 is also bifurcation and is not end of a ridge. Under the circumstances the prosecution has failed to prove beyond doubt that the thumb-impressions on the muster-rolls are forged. The prosecution has also failed to show that no work, in fact, has been executed in respect of which these payments were made as per these 13 muster-rolls. We, therefore, find no reason to interfere with the acquittal.

37.11 ADMISSIBILITY OF FOOTWEAR MARKS[20]

Author's Summary

Track marks evidence is generally dubbed as rudimentary science. However in this case the trial court, the high court and the Supreme court accepted the track evidence to identify the culprits evidence:

Highlights italicised

20. *Pritam Singh v state of Punjab,* AIR 1956 SC 415 : 1956 Cr LJ 805 (SC).

Relevant Extracts (verbatim)

We are unable to accept this contention. The science of identification of footprints is no doubt a rudimentary science and not much reliance can be placed on the result of such identification. The track evidence, however, can be relied upon as a circumstance which, along with other circumstances, would point to the identity of the culprit though by itself it would not be enough to carry conviction in the minds of the court.

The shoes had been recovered in the search of the house of the accused and the result of the search was proved by calling the search witnesses whose evidence was believed by both the courts with the result that these shoes, having been recovered from his house, the ownership of the shoes was *prima facie* established to be his even though the accused had alleged that he has not been staying in the house but had rented the house for some acquaintance of his.

There was evidence to show that he and his wife were staying there right up to 10 A.M. on June 9, 1953 on which day the search was made and if this evidence was believed it would go to establish his ownership of the shoes. If he was the owner of these shoes it was quite legitimate to compare the impressions made by these shoes with the mould prepared from the footprints on the spot.

The learned additional sessions judge, however, in order to derive further assurance attempted, in the examination of the accused under section 342, Code of Criminal Procedure to see if these shoes which had been recovered from the house of the accused fitted his feet. If the accused has refused to accede to this suggestion of the learned additional sessions judge he would have been justified in doing so and there is no provision in law by which this demonstration could have been made.

The accused, however, agreed to do so and on the shoes being tried on his feet. It appeared that they fitted his feet. Realising, however, that the result of this demonstration would be adverse to his defence he complained that the shoes were too tight for his feet.

The learned additional sessions judge, however, thought otherwise and recorded his impressions accordingly. This type of evidence was very strongly criticised by the learned counsel for the appellant as real evidence which was not justified at all by the provisions of section 539B, Code of Criminal Procedure or otherwise and it was urged that it was a matter which prejudiced the defence of the accused.

The learned additional sessions judge was certainly not entitled to allow his view or observations to take the place of evidence because such view or observation of his could not be tested by cross-examination and the accused would certainly not be in a position to furnish any explanation in regard to the same.

The whole thing appears to have been done with the consent of the accused and the only criticism which could be legitimately levelled was against the observation recorded by the learned additional sessions judge that:

> *to all appearances they quite fitted the feet of the accused even though he complained that the shoes were too tight for his feet.*

This observation could not carry the matter any further for the prosecution and the only fact which could be relied upon by the prosecution was that the shoes apparently fitted the feet of the accused and the learned additional sessions judge and the assessors were entitled only to take into account the fact that the shoes apparently fitted the feet of the accused though he complained that they were too tight for his feet.

This was an ocular demonstration and the result of such ocular demonstration could certainly be taken into account by the learned additional sessions judge and the assessors and they were entitled to come to their own conclusions taking into account the further fact that the accused did complain at the time that the shoes were too tight for his feet.

The evidence of the trackers and also the fact that shoes were found in the house of the accused and the impressions made thereby tallied with the moulds prepared from the footprints on the spot were even otherwise enough to establish the identity of the footprints and point to Pritam Singh Fatehpuri as one of the culprits.

The case of Pritam Singh Lohara in regard to the track evidence was no different. In spite of the fact that none of the witnesses of the occurrence nor Pritam Singh, the driver, had stated anywhere before that Pritam Singh Lohara had a limp in his gait, the result of the evidence of the trackers was sufficient to establish that one of the culprits made footprints which showed that his way of walking was outwards and he put his right foot more outwards than the left.

This was quite characteristic of Pritam Singh Lohara by reason of the limp in his gait and this was further demonstrated by the impressions which he made when he walked in the district jail with the shoes given to him there on the sandy patch which was specially prepared for the purpose.

This evidence in regard to Pritam Singh Lohara also was believed by both the courts below as sufficient to establish his identity as one of the culprits and we are not prepared to differ from their appreciation of the evidence. The track evidence, therefore, was a circumstance which was available to the prosecution against Pritam Singh Fatehpuri and Pritam Singh Lohara.

37.12 NAKED FOOTPRINT MARKS[21]

Author's Summary

It is a case in which naked footmarks were compare by the High Court judge himself and the evidence on the marks was discussed threadbare. The court ultimately came to the conclusion:

'*The comparison has thus stood the test well and, under the circumstances these foot impressions in blood near the place of the incident which are proved to be those of the accused-appellant Surajpal Singh by preponderance of probabilities are a strong incriminating circumstance against the accused-appellant Surajpal Singh for which he has not accounted'.*

Highlights italicised

We examined and compared the footprints for ourselves and in our opinion, there is such a remarkable similarity between the admitted footprints of the accused-appellant, Surajpal Singh, and the footprints in blood found on the spot that there is a high degree of probability that the footprints in blood found on the floor of the verandah of the accused-appellant, Surajpal Singh, are the footprints of the accused-appellant.

In *Pritam Singh v State of Punjab,*[1] Bhagwati J, speaking for the court said:

> *The science of identification of footprints is no doubt a rudimentary science and not much reliance can be placed on the result of such identification. The track evidence, however, can be relied upon as a circumstance which, along with other circumstances, would point to the identity of the culprit, though by itself it would not be enough to carry conviction in the minds of the court.*

It was, however, unfortunate that it was not brought to the notice of the court that the identification of persons from footprints has many facets and all these facets could not be clubbed together, and science of identification from footprints be dubbed as a rudimentary science.

The identification of persons from footprints may broadly be classified as under:

1. Identification from footprints when the footprints show ridge characteristics. In such cases, the science is as accurate as the science of fingerprints. The prints of the foot of a person show ridge characteristics of his fingers and may be used in a similar way for the identification of persons from similarity of ridge characteristics.

21. *Surajpal Singh v State of Madhya Pradesh*, 1972 Cr LJ 1668 : 1972 MPWR 394 : 1972 MPLJ 1029.

2. Identification from footprints which have special characteristics apart from ridge, etc. Some feet have special characteristics such as a scar at a particular place, an extra or missing toe, a deformative peculiarity. In this case, the value of identification is proportional to the number of peculiarities.

3. Identification of footprints, which show neither ridge characteristics nor other special peculiarities. This is what we usually understand by identification from footprints though quite erroneously because it is only one of the three categories of identification from footprints. This is based on what is known as "Gayer System" as propounded by GW Gayer, I.P., in his book.[22] In this system which is based on the system of the "Khojis", who were professional trackers of Rajputana, a foot has 12 features namely the five toes called Anguta, Dusri, Tesri, Chouthi and Chichi, the head line of the ball of the foot called Zanjiri, the ball of the foot called Pab, the instep called Talli, the length of the foot from uppermost point of Anguta to the lower most of the heel (Eri) called Chab, the heel called, Eri, the inner margin of the foot called, Bari Assi and the outer margin of the foot called Choti Assi. According to the author, every one of the twelve features has as much characters as the features of a face. Once a pupil learns to distinguish them at a glance, he can recognise a person from his foot impressions as easily as he can from his face. These features and their characteristics are compared with reference to three guidelines; the first is a vertical line going from the highest point of the big toe (Anguta) to the centre of the heel (Eri), the second line is at right angle to the aforesaid line running under the base of the little toe (Chichi) and the third joins the highest point of the big toe to the top of the little toe and joins the second line. The author further says at page 3:

> *It is obvious that every individual's footprint must have a distinct individuality for even if there were only three common types of each of the features; and we had nothing else to go on, the total possible number of different types would be 531441, so that, on the average, two feet in about every million would be similar. A careful study of the illustrations and of the text will show that these figures do not err on the side of exaggeration.*

Again at page 6, paragraph 30, the author to avoid possibilities of error in identification says:

> *When two impressions are being compared with each other with the object of finding out if both have been made by the same foot one thing must be clearly understood, if they are impressions of the same foot they will agree in all essential points and there will be no points of disagreement. If there are points of disagreement and these have not obviously been caused by some peculiarity or irregularity of the ground, or by some accident, it should be at once admitted that the impressions are those of different feet.*

Rejecting the contention that the study of footprints is not a science in *Din Muhammad v Emperor*[23] , the court of the Judicial Commissioner at Nagpur (H.J. Stanyon and H.F. Hallifax, A.J. Cs.) as far back as in 1914 held:

> *Now the knowledge of handwriting and that of finger impressions have been systematised and arranged under general truth and principles by many writers and pursued by many enquiries, and they are both sciences in which a great deal of progress has been made. The knowledge of footprints has similarly been systematised and pursued by trackers, mainly uncivilised and ignorant people in all other respects, all over the world, and also at the Saugar Police Training School under Mr. G.W. Gayer, who has arranged the knowledge he obtained from other seekers and from his own observations and experiments in a valuable monograph entitled 'Footprints'. The matter is, therefore, undoubtedly a science and the opinion of a person specially skilled in it is a relevant fact, under section 45 of the Evidence Act.*

22. GW Gayer, *Foot Prints: An Aid to the Detection of Crime for the Police and Magistracy*, 1st Edn, 1909.
23. *Din Muhammad v Emperor,* Central Provinces Police Gazette, decided on 27 May 1914, pp 125-130.

In the instant case the points of similarities are 9 in respect of the right foot impressions, 10 in respect of the left foot impressions and the points of dissimilarities are three only in each case which have been explained by the expert (P.W. 13) is due to the different densities of the media in which the foot impressions were made namely, printer's ink and blood. The comparison has thus stood the test well and, under the circumstances these foot impressions in blood near the place of the incident which are proved to be those of the accused-appellant Surajpal Singh by preponderance of probabilities are a strong incriminating circumstance against the accused-appellant Surajpal Singh for which he has not accounted.

37.13 CONVICTION ON FIREARM EVIDENCE ALONE[24]

Author's Summary

It is a landmark judgment on Forensic Ballistics. In this case of murder, the SC ruled that conviction of a murderer can be based upon ballistics expert's opinion alone. They have cited numerous authorities to support the view**. SC Verdict:**

'*If there is no reason to think that there is any room for error in matters of this kind and it is safe to accept the opinion of the expert, then clearly it is established that the cartridge Ex. 1, found near the cot of Daya Ram, was fired from the pistol Ex. III produced by the appellant'***.**

Highlights italicised

Relevant Extracts (Verbatim)

While the sessions judge believed the testimony of the eyewitnesses, the learned judges of the High Court were of the opinion that they were unable to accept the assertion of the eye-witnesses that they actually saw the appellant with a pistol by the bed-side of the deceased. The High Court, however, relied upon the circumstantial evidence in the case in upholding the conviction of the appellant. There was motive for the crime and a few days before the killing of Daya Ram, the appellant had held out a threat against him. The appellant was arrested fourteen miles away from his village which is the place of occurrence. He produced a pistol (Ex. III) from his house in circumstances which clearly showed that he only could have known of its existence there. The opinion of the firearms expert clearly established that the cartridge (Ex. I), found near the cot of Daya Ram, was fired with the pistol (Ex. III) produced by the appellant. All these circumstances, in the opinion of the High Court left no doubt that the appellant murdered Daya Ram by shooting him with his pistol.

It was next urged on behalf of the appellant, that it was impossible for a cartridge to have been near the cot of Daya Ram, because after the shot had been fired the cartridge would still remain in the barrel of the firearm. This again is pure speculation. That the cartridge was ejected from the firearm is certain. Why it was ejected, none can say. It may be that the miscreant reloaded his weapon to meet any emergency. The evidence of the sub-inspector is clear that on his arrival at the place of occurrence the cartridge Ex. 1 was handed over to him by the witness Khamani who cannot be said to be unfavourable to the appellant. The courts below had no reason to disbelieve the evidence in the case that the cartridge Ex. 1 was found near the cot of Daya Ram and we can find no extraordinary circumstance to justify as saying that the courts below took an erroneous view of the evidence.

The real question is, whether it is safe to act upon the opinion of the firearms expert that the cartridge Ex. 1 was fired from the pistol Ex. III produced by the appellant and none other, because without that evidence the circumstantial evidence in the case would be insufficient to convict the appellant of the crime of murder. The opinion of the firearms expert, based on the result of his tests, does not seem to have been

24. *Kalua v State of Uttar Pradesh*, AIR 1958 SC 180 : 1957 SCR 187 : 1958 Cr LJ 300 (SC).
Also see *Meera Puri v State of Nagaland*, 1971 Cr LJ 539 : 1971 Assam LR 22 (Ass and Nag).

challenged in cross-examination or before the High Court. If there is no reason to think that there is any room for error in matters of this kind and it is safe to accept the opinion of the expert, then clearly it is established that the cartridge Ex. 1, found near the cot of Daya Ram, was fired from the pistol Ex. III produced by the appellant.

To satisfy ourselves we have looked into the works of some authors dealing with the marks left on cartridge and shell cases by firearms in order to ascertain that there is no error in the opinion of the firearms expert in the present case. Kirk in his book *Crime Investigation* at page 346 states:

> ***"Fired cases are less often encountered in the criminal investigation than are bullets, but when found they are usually of greater significance because they receive at least as clear markings as do bullets, have a greater variety of such markings, and are not ordinarily damaged in firing…***
>
> ***The questions which may be asked as a result of finding such materials are similar to those that require answers when only bullets are located. In the ordinary case, quite definite answers can be given. This is true both of shotgun shells and of cartridge cases from pistols, revolvers, and rifles....In general, it is possible to identify a certain firearm as having fired a particular shell or cartridge, it is often possible to identify the type of make of gun which fired it, though in many instances this must be tentative or probable identification only".***

After dealing with the marks left by breech-block, firing pin impressions, marks from extractors and ejectors, marks due to expansion, magazine marks and loading mechanism marks, he states:

> ***"Summarising, the cartridge or shell case usually carries markings which are quite distinctive of the gun in which the charge is fired, and can be used for positive identification of the latter. These marks arise from a variety of contacts with various parts of the gun, an analysis of which is useful in determining the type of weapon in case no suspected gun is available... Thus, the recovered shell or cartridge case is one of the most useful types of physical evidence which can be found in shooting cases."***

Soderman and O'Connell in their book *Modern Criminal Investigation* also deal with the subject and they refer to the marks from the firing pin, the extractor, the ejector, and the breech block. After referring to the comparison being made of the cartridge or shell fired from a firearm for the purpose of test, they state at page 200:

> *"If they are in the same position in relation to one another and their general appearance is the same, one may conclude that they have been fired from a pistol of the same make. An absolute conclusion about the origin of the shells, however, can be reached only after a photomicrographic examination of the markings from the breech block on the rear of the shell..."*
>
> *Identification, with the aid of the enlargement, should not prove difficult. The characteristic scratch can be easily seen. A photograph of the incriminating shell and one of a comparison shell should be pasted side by side on cardboard, and the characteristic marks should be recorded with lines and ciphers, following the same method as that used in the identification of fingerprints".*

In Taylor's book on *Medical Jurisprudence*, 10th Edn., Vol. 1, at p. 459, it is stated:

> *"It is never safe to say that a cartridge case was not fired from a given pistol unless the marks are quite different, and a case which bears no marks at all may quite well have been fired from the same pistol as one which leaves well-defined marks. In general, however, though it is unlikely that all marks will be equally good, it is usually possible to obtain definite information from the marks of the firing pin, extractor, ejector or breech-block on the base or rim or from grooves or scratches on the surface. In weapons of the same manufacture the marks are of the same general nature, but in each weapon there are individual differences which usually enable it to be definitely identified".*

The expert's evidence, in this case, shows that he had fired test cartridges from the pistol Ex. III. He found the individual characteristics of the chamber to have been impressed

upon the test cartridge Exs. 9 and 10 and that exactly identical markings were present on the paper tube of the cartridge Ex. 1. He made photomicrographs of some of these individual marks on Exs. 1 and 10. In giving his reasons for his opinion, the firearms expert stated that every firearm has individual characteristics on its breech face, striking pin and chamber. When a cartridge is fired, gases are generated by the combustion of the powder, creating a pressure of 2 to 20 tons per square inch. Under the effect of this pressure the cap and the paper tube of the cartridge cling firmly with the breech face, striking pin and chamber and being of a softer matter the individualities of these parts are impressed upon them. By firing a number of test cartridge from a given firearm and comparing them under a microscope with the evidence cartridge, it can definitely be stated, if the marks are clear, whether the evidence cartridges had been fired or not from that firearm. It seems to us that the firearm expert made the necessary tests and was careful in what he did. There is no good reason for distrusting his opinion. The learned judges of the High Court examined the photomicrographs in question and were satisfied that there was no ground for distrusting the evidence of the expert. They were accordingly justified in coming to the conclusion that the cartridge Ex. 1, found near the cot of Daya Ram, was fired from the pistol Ex. III produced by the appellant from his house. There can, therefore, be no room for thinking, in the circumstances established in this case, that anyone else other than the appellant might have shot Daya Ram. He was, therefore, rightly convicted for the offence of murder.

The appeal is accordingly dismissed.

37.14 PELLETS IDENTIFICATION[25]

Author's Summary

It is a landmark SC judgment which appraised the linkage of buckshot with the shotgun in a case of murder and found it creditworthy. It had not been done before. It has important ramifications, the most important being that the smooth bore firearm (including improvised firearms) can be linked to the fired ammunition through them.

Further the court ruled that photographs are not necessary.

Relevant Extracts (Verbatim)

Judgment with Criminal Appeal Nos. 98-102 of 1999 and Criminal Appeal Nos. 109-114 of 1999 are filed by the State of Madhya Pradesh through CBI and the Criminal Appeal Nos. 103-108 of 1999 are filed by the Chhattisgarh Mukti Morcha. All these appeals arise out of the common judgment passed by the High Court of Madhya Pradesh on 26-6-1998. Nine accused persons were tried by the Second Addl. Sessions Judge, Durg, M.P. Accused Nos. 1 to 8 were charged for the offence under section 302 read with section 120B IPC. The 9th accused was charged under section 302 read with section 120B, and in the alternative, section 302 read with section 34 IPC and section 25(1)(A) and section 27 of the Arms Act. The Sessions Judge acquitted A-6 Naveen Shah, A-7 Chandrabaksh Singh and A-8 Baldev Singh Sandhu. A-1 Chandrakant Shah, A-2 Gyan Prakash Mishra, A-3 Avdhesh Rai, A-4 Abhay Kumar Singh, A-5 Moolchand Shah and A-9 Paltan Mallah @ Ravi were convicted by the Sessions Judge for the offence under section 302 read with section 120B. A-9 Paltan Mallah was found guilty of the offence punishable under section 302 IPC and sentenced to capital punishment whereas other accused were sentenced to life imprisonment. The High Court by the impugned Judgment acquitted all the accused of the charges framed against them.

Deceased Shankar Guha Niyogi was a popular, powerful trade union leader in the industrial region of Bhillai, Durg, which was part of the then State of Madhya Pradesh.

25. *State of Madhya Pradesh v Paltan Mallah,* AIR 2005 SC 733 : 2005 AIR SCW 455 : 2005 Cr LJ 918 (SC).

Deceased Shankar Guha Niyogi had been working for the welfare of the labour demanding living wages, bonus, reinstatement of retrenched workers and he organised the workers of the various industrial units at Bhillai and Durg. The labourers had an organisation by name "CHATTISGARH MUKTI MORCHA" (hereinafter being referred to as CMM") and deceased Niyogi became a leader of this organisation. He was leading the labourers working at Rajaram Mines area which was a main source of raw material iron ore for the Bhillai Steel Plant at Durg. In the year 1989, there was an agitation by the workers of industrial unit by name ACC, which is a leading cement manufacturer. A settlement was reached at the instance of deceased Niyogi. The workers in other industrial establishments sought the help of deceased Niyogi to solve their problems. In the year 1990, he came to Bhillai and started occupying quarter No. MIG 1/55 of HUDCO. He stayed there with his servant Bahal Ram. The other members of his family continued to stay near Rajhara. Deceased Niyogi set up an office for CMM at MIG-2/273 HUDCO. In the year 1990, there was widespread labour movement against the management of various industrial units such as Simplex, Kedia, B.E.C. B.K, etc. According to the prosecution, the management of these industrial units started opposing the labour movement and there was even physical attack on some of the leaders of CMM. One Uma Shankar Rai, a leader of CMM was fatally assaulted by the agents of the industrialists. Deceased Niyogi apprehended serious threat to his life from the industrialists, especially from Simplex and Kedia Group of Industries. He made notes in his diary regarding the apprehension of danger from the management of these industrial units. On 27-9-1991, he had gone to Raipur and there he met one Rajendra Sail, Secretary General of PUCL and reporter N.K. Singh of "India Today". He expressed an apprehension of danger to his life from Kedia and also from A-5 Moolchand Shah and A-l Chandrakant Shah of Simplex Group. On 27-9-1991 at about midnight, he left Raipur for Bhillai and reached his quarter No. MIG- 1/55 of HUDCO and went to bed. His servant Bahal Ram was occupying the neighbouring room. In the night, Bahal Ram heard a noise like bursting of crackers and he rushed to the room of Niyogi and found Niyogi writhing in pain on his bed. The window was found open. Bahal Ram called for help of the neighbour Sripad Mategaonkar. Few workers from the CMM came to the place and it was found that Niyogi had been shot. He was immediately taken to the Sector 9 Hospital of Bhillai. Before reaching the hospital, Niyogi succumbed to the gun shot injuries. Post-mortem examination was conducted by a team of doctors and they opined that death was due to bullet injuries.

Preliminary investigation was carried out by PW-182 Deputy Superintendent of Police Shri M.G. Agarwal. There was agitation by the workers that investigation shall be conducted by the Central Bureau of Investigation and the Government of Madhya Pradesh requested the Union of India seeking help of the Central Bureau of Investigation. As part of police investigation, PW-182 visited the scene of occurrence and got prepared map of the site and he took steps to see that viscera of the victim was sent for laboratory tests. He took into custody the pellets recovered from the body of Niyogi. He took statements from Bahal Ram, the servant and also from the widow and daughter of deceased. He got prepared photograph Exh. P-180 to P-196. He got report from Serum Science and Chemical Analysis which are marked as Exh. P-430 to P-432. He recorded statements of various other witnesses. Accused A-3 Avdhesh Rai was taken into custody on 13-10-1991. On 1-11-1991, he seized diary of deceased Niyogi and on 9-11-1991 he handed over the investigation to CBI officials.

PW-187 R.S. Dhankad took over the investigation along with PW 192 R.S. Prasad. PW-187 held search of Oswal Industry. He recorded the statements of Zakkiruddin on 21-11-1991. This witness identified the photographs of A-2 Gyan Prakash Mishra and A-3 Abhay Kumar Singh. PW-192 conducted further investigation of the case along with other officers. On 10-11-1991, he seized the window curtains from the house of Niyogi. On 15-11-1991, he conducted searches of the business premises of Jain and Shah and Company, 108 A. Khan Goga Complex and recovered articles under Exh. P-297.

After the arrest of accused Paltan Mallah on 25-8-1993, he got recovered .12 bore country made weapon, 13 live cartridges of 12 bore, a foreign made

revolver, 6 live cartridges of .38 bore and a red colour Suzuki Motorcycle. He sent Exhs. P-403 and 404 to Central Forensic Laboratory (CBI), New Delhi. He conducted various other searches and recovered incriminating articles from the other accused. After investigation, the final report was filed.

On the side of prosecution PW-1 to PW-192 were examined by the trial court.

The High Court by the impugned judgment acquitted all the accused and that is challenged before us.

Then the most important item of evidence against the accused, Paltan Mallah, is the report of the ballistic expert. PW-192, the Deputy Superintendent of Police of the CBI deposed that after the arrest of the appellant Paltan Mallah on 25-8-1993, he recovered one .12 bore improvised pistol, 13 live cartridges .12 bore, one foreign made pistol, 6 live cartridges of .38 bore and a motorcycle. The improvised pistol, the foreign made pistol and the cartridges were sent for examination by the ballistic expert to the Central Forensic & Science Laboratory, New Delhi. During the post-mortem of the deceased Shankar Guha Niyogi, three pellets were extricated from his body. These pellets were sent to Forensic Laboratory at Sagar and thereafter they were deposited in the court by PW-192 and these pellets were also later on obtained from the court and sent for examination by the CFSL. PW-159, the ballistic expert conducted detailed laboratory test-fires and microscopic examination and he gave Exh. P-398 report wherein he opined that three lead pellets marked P-1 to P-3 must have been fired from a .12 bore improvised pistol. He deposed that he had prepared the report on the basis of the microscopic examination and he had also taken photographs of the pellets and Exh. P-398 are the work-sheets of the report prepared by him.

The evidence of PW-159 and his report are seriously challenged by the counsel for the respondent accused. He extensively referred to the text books written by foreign ballistic experts such as Burrad, Hatcher and Taylor. It was argued that in the instant case, the weapon was an improvised pistol and the barrel was not grooved and there was absolutely no question of any identifiable marking coming on the pellets to enable the expert to give any opinion whatsoever. Reliance was placed by him on the observations of this Court in Ram Avtar v Ram Dhavi, (1997) 2 SCC 263: 1996 AIR SCW 4264: AIR 1997 SC 107: 1996 All LJ 1908 wherein this Court relied on the opinion of J.S. Hatcher in his text book of Firearms & Investigation to the effect that "unless there were rifling marks in the bullets which were not defaced by the entry in the bodies of the victims, no expert can ordinarily and generally give an opinion. It was also pointed out that in the case of improvised pistol, it was difficult to assume that the ballistic expert could have found identifying marks on the pellets. The evidence given by the ballistic expert was questioned in great detail. He was cross-examined extensively by counsel for all the accused. He deposed in the cross-examination that when these pellets are fired, then they among themselves would press each other inside the barrel [on inside parts] their effect could be on one side of inner side of barrel, they will take special individual mark on them and these marks will be in the form of a line on the pellets and if the barrel is tight then pellets will be more rubbed, and on more parts, lines will come. If barrel is tight then half part of the pellets are pressed and the barrel was nicely tight and the witness himself said that in the test fire which he did on all of the six pellets good marks of barrel had come. He had also stated that he had taken micro-photograph of only one pellet and had compared all pellets but he had not made any separate comparative record or photograph.

It was argued that micro-photographs were not produced and mere observation by the expert—was not sufficient and that he should have produced these photographs. We do not think that there was any such necessity to produce the micro photographs when the expert has given convincing reasons to support his opinion.

This Court. in *Ramanathan v State of Tamil Nadu,* (1978) 3 SCC 86 : 1978 Cr LJ 1137 : AIR 1978 SC 1204 para 26 held that the production of such photographs is not necessary and such a plea was rejected. In paragraph 26, it was held as under:

> *"It is true that there has been considerable difference of opinion amongst investigators regarding the use of photographs in a court for the purpose of illustrating the matching of the markings, and while it may be that microscopic photographs, when taken with due care and in the best of conditions, may enable the evidence to be placed on the record in a visible form, it cannot be denied that a court would not be justified in rejecting the opinion of an expert who has examined the markings under the comparison microscope simply for the reason that he has not thought it necessary to take the photographs. It is therefore not possible for us to reject the evidence of Ramiah (PW-23) who has categorically stated that he had compared the land and groove markings on the bullets under a comparison microscope, simply because he did not think it necessary to take the photographs."*

In the case of the respondent-accused Paltan Mallah, there is overwhelming evidence to prove his complicity in the crime. The recovery of the improvised pistol at his instance, which is proved to have been used for causing the death of Shankar Guha Niyogi; and the evidence of the ballistic expert coupled with two extra-judicial confessions made to PW-105 made PW-124 support the prosecution case fully. There is also prosecution evidence to the effect that the accused had got accessibility to the weapons and that he was staying at the place of occurrence and doing various jobs. It is also established that accused Paltan Mallah is involved in other offences relating to firearms. Though there is no direct and convincing evidence against other accused, the case against Paltan Mallah is proved beyond reasonable doubt. He was acquitted by the High Court on fanciful reasons. The evidence of extra-judicial confessions was rejected without any valid reasons. The report of the ballistic expert also was not appreciated in the correct perspective by the High Court. In our view, the Division Bench seriously erred in acquitting the respondent-accused Paltan Mallah.

In the result, we reverse the acquittal of the respondent-accused Paltan Mallah. The incident leading to these appeals had taken place as early as 1991. As there is a long lapse of time, we do not think that the sentence of death imposed upon him by the Sessions Court is justified in the circumstances. We set aside the acquittal of respondent-accused Paltan Mallah and find him guilty of the offence punishable under section 302 IPC and sentence him to undergo imprisonment for life.

37.15 GUIDELINES FOR SELF-DEFENCE IN GUNSHOT FIRE[26]

Author's Summary

It is a case of murder in a family dispute; a 12 bore shotgun was used. The main point to determine was whether the injured 2 eyewitnesses were really injured or not . The absence of pellets in their injuries nailed the lie. The SC believed that the firing/killing was in self-defence. The SC also laid guideline to identify a self-defence case.

Highlights italicised

Relevant Extracts (Verbatim)

Brief facts which are necessary to dispose of this appeal are recapitulated as under:—

> The dispute is between very close and intimate family members. Deceased Gurcharan Singh was the brother of Bakhtawar Singh and uncle of Darshan Singh. He was the father of Gurdish Singh, PW-7, the informant. The agriculture fields of both brothers, Gurcharan Singh and Bakhtawar Singh were situated adjoining to each other. According to the prosecution, on 15-7-1991 at about 8 a.m. Gurdish

26. *Darshan Singh v State of Punjab*, AIR 2010 SC 1212 : 2010 AIR SCW 832 : 2010 Cr LJ 1393.

Singh, PW-7 and his father, Gurcharan Singh were irrigating their aforesaid fields and were also mending its ridges and at that time Gurdev Singh, PW-8 and Ajit Singh were also present there. In the meantime, Darshan Singh and Bakhtawar Singh came there from the side of their fields raising lalkaras and abused the complainant party. Darshan Singh, accused was armed with D.B.B.L. gun and his father Bakhtawar Singh was carrying a Gandasa and they were saying that they would teach a lesson to the complainant party for cutting the ridges.

5. According to the further story of the prosecution, Bakhtawar Singh gave a Gandasa blow causing injuries on the chest of Gurcharan Singh. Gurcharan Singh was also having a Gandasa with him and in order to save himself he also caused injury on the head of Bakhtawar Singh. Thereafter, Darshan Singh fired two shots from his licensed gun which hit Gurcharan Singh in the chest and some of the pellets hit Gurdish Singh PW-7 on his left upper arm and Gurdev Singh, PW-8 on his left thigh. Gurcharan Singh fell down and died at the spot. Gurdish Singh and others retraced their steps in order to save themselves. Both the accused in order to save themselves ran towards their respective houses. The prosecution examined 11 witnesses. Dr. Mukesh Gupta, PW-4 who conducted the post-mortem examination found the following injuries on the dead body of Gurcharan Singh:—

"1. There were 14 wounds in an area of 20 cm x 18 cm on the left side of the chest above the nipple. One of the wounds which was above the nipple was having inverted margins. A wad was recovered from this wound. This wound was 1 cm x 1 cm. The 9 wounds which measured 0.75 cm x 0.75 cm which were on the chest and shoulder also had inverted margins. Out of these wounds 6 were found to entering chest cavity and 6 pellets were recovered from the chest cavity. The remaining 3 wounds were having everted margins. These were near the axilla and each wound measured 1 cm x 1 cm. One of the 14 wounds which measured 0.75 cm x 1.5 cm was having inverted margins. It was skin deep and was on the shoulder, upper part of humerous and clavicle bones were found to be fractured. 4th and 5th rib of the left side of the chest were also found to be fractured.

2. There were 7 wounds in an area of 20 cm x 8 cm on the upper part of the chest on its right side above the nipple. Out of these wounds 3 wounds measuring 0.75 cm x 1 cm each was having inverted margins, these were skin deep. 2 wounds were having everted margins having a dimension of 1 x 1 cm each near the axilla. A pellet was recovered from near the axilla. The remaining 2 wounds were near the top of right shoulder measuring 0.75 x 1.5 cm each with inverted margins. These were skin deep.

3. An incised wound 8 cm x 0.5 cm skin deep on the left side of the chest 3 cm above the nipple. It was horizontally placed."

10. Dr. Mukesh Gupta found following injury on the person of Gurdev Singh:—

"An abrasion measuring 1 cm x 0.5 cm on the front and inner side of left thigh. It was a superficial abrasion reddish in colour, over the junction of upper l/3rd and lower 2/3rd of the thigh. There was damage to the pajama corresponding to the injury."

11. *According to the doctor, the injury was simple in nature and was caused within 24 hours.*

Doctor also found injury on Gurdish Singh to be superficial. The same reads as under:—

"A very superficial abrasion 1 cm x 0.5 cm on the upper side of left upper arm 12 cm above the elbow. It was reddish in colour."

12. It may be relevant to mention that Dr. M.S. Gill, PW-5, who conducted the medical examination of Bakhtawar Singh found the following injuries on his person:—

"1. An incised wound 7 cm x 0.5 cm on the parietal region of the right side of head. It was placed anterior posteriorly. The wound was bone deep and 4 cm above the right pinna, clotted blood was present."

13. According to the doctor, this injury was caused by sharp-edged weapon.

* * *

21. The trial court after discussing the entire evidence came to the conclusion that two counter versions of the case have been presented and, in the view of the trial court, the defence version is more probable and nearer to the truth for the following reasons:

(i) The delay in lodging the FIR impels the court to scrutinise the evidence of witnesses regarding the actual occurrence with greater care and caution.

(ii) The crucial point to be decided in this case was that who was the aggressor or which of the parties can have the motive to open the attack?

The trial court held that "if the accused were already cultivating the land as per compromise, then it does not appeal to reason as to why they would feel aggrieved. On the other hand there was strong motive for Gurcharan Singh to assault the accused person as he has resiled from the compromise."

(iii) The next crucial point according to the trial court was as to where the incident took place? According to the trial court the incident had taken place in the field of the accused.

(iv) According to the trial court, the presence of the prosecution witnesses Gurdev Singh and Gurdish Singh at the time of alleged occurrence is highly doubtful. Dr. Mukesh Gupta stated that the injuries on Gurdev Singh and Gurdish Singh could be caused by friendly hands and can be self-suffered.

(v) No pellet was recovered from the injuries of the prosecution witnesses namely, Gurdev Singh and Gurdish Singh. The possibility of the injuries on their persons having been fabricated at a later stage cannot be ruled out.

The trial court found that, in the instant case, it appeared that the inquest report was prepared first and the FIR was prepared at some later stage because there was no mention about the injuries of Gurdev Singh and Gurdish Singh in the inquest report, whereas this fact is mentioned in the FIR. According to the prosecution case, Gurdish Singh suffered a pellet injury on his left upper arm whereas, Gurdev Singh was hit on his left thigh. This was so mentioned in the FIR. If it was so, this fact would have been mentioned in the inquest report or the Investigating Officer must have prepared their injury statement, but no such injury statement was prepared at the spot nor their medical examination was got done.

In the cross-examination, Om Prakash ASI had admitted that he came to know about the injuries of Gurdish Singh and Gurdev Singh only when they gave their supplementary statements at the bus stand. The finding of the trial court is that the injuries were fabricated with the connivance of the Investigating Officer just in order to make Gurdish Singh and Gurdev Singh stamp witnesses.

(vi) Gurdish Singh PW-7 had admitted that his father Gurcharan Singh was face to face when Bakhtawar Singh gave Gandasa blow from above to downward vertically on the chest of Gurcharan Singh. However, Dr. Mukesh Gupta contradicted him and stated that injury No. 3 on the person of Gurcharan Singh was skin deep and was horizontally placed and was possible by a fall on a sharp edged weapon.

From this it can safely be concluded that it was not Bakhtawar Singh who gave Gandasa blow to Gurcharan Singh in the manner as suggested by the prosecution. It is most likely that Gurcharan Singh suffered injury No. 3 by a fall on his own Gandasa and this was the reason that the wound was only skin deep.

The story put forth by the prosecution that Gurcharan Singh was cutting weeds of ridges with Gandasa is not believable. Gurdish Singh stated that he was collecting the cut weeds. They were not having any Kassi or Khurpa and it was not possible to cut weeds of ridges with Gandasa.

(vii) The trial court came to a clear conclusion that Bakhtawar Singh was injured at point 'F' as shown in the site plan at the hands of Gurcharan Singh (deceased). Gurcharan Singh after causing that injury forwarded towards Darshan Singh armed with Gandasa and at that point Darshan Singh had no option but to open fire and Gurcharan Singh died of that firearm injury. The trial court came to the definite conclusion that Darshan Singh fired a shot in his right of private defence.

(viii) The trial court after marshalling the entire evidence came to the conclusion that seeing from all angles, the probabilities of the case are much more in favour of the defence than in favour of the prosecution.

The possibility of the injuries having been caused to Gurcharan Singh by Darshan Singh in exercise of private defence cannot be ruled out. Thus, the prosecution has failed to prove its case against the accused person beyond any reasonable doubt and the benefit has to be given to them.

58. The following principles (for self-defence) emerge on scrutiny of the judgments[27]:

(i) Self-preservation is the basic human instinct and is duly recognized by the criminal jurisprudence of all civilized countries. All free, democratic and civilized countries recognize the right of private defence within certain reasonable limits.

(ii) The right of private defence is available only to one who is suddenly confronted with the necessity of averting an impending danger and not of self-creation.

(iii) A mere reasonable apprehension is enough to put the right of self-defence into operation. In other words, it is not necessary that there should be an actual commission of the offence in order to give rise to the right of private defence. It is enough if the accused apprehended that such an offence is contemplated and it is likely to be committed if the right of private defence is not exercised.

(iv) The right of private defence commences as soon as a reasonable apprehension arises and it is co-terminus with the duration of such apprehension.

(v) It is unrealistic to expect a person under assault to modulate his defence step by step with any arithmetical exactitude.

(vi) In private defence the force used by the accused ought not to be wholly is proportionate or much greater than necessary for protection of the person or property.

(vii) It is well-settled that even if the accused does not plead self-defence, it is open to consider such a plea if the same arises from the material on record.

(viii) The accused need not prove the existence of the right of private defence beyond reasonable doubt.

(ix) The Indian Penal Code confers the right of private defence only when that unlawful or wrongful act is an offence.

(x) A person who is in imminent and reasonable danger of losing his life or limb may in exercise of self-defence inflict any harm even extending to death on his assailant either when the assault is attempted or directly threatened.

In the instant case after marshalling and scrutinising the entire prosecution evidence, we are clearly of the view that the trial court's view is not only the possible or plausible view but it is based on the correct analysis and evaluation of the entire evidence on record. Rationally speaking, no other view is legally possible.

65. Consequently, this appeal is allowed and the impugned judgment of the High Court is set aside and the judgment of acquittal of the trial court is restored. The role attributed to the appellant is fully covered by his right of private defence.

37.16 NO GUN WORK[28]

Author's Summary

It is a case of murder in which a bar tender was shot dead. The alleged culprit (finally convicted) allegedly fired one shot. The police recovered 2 fired shells from the scene. Firearm(s) was not recovered. The experts failed to interlink/de-link the 2 shells. Defence urged that the second shot, fired by another unknown person, might have killed the victim.

The court was misled to believe that firearms are needed to link/delink the fired shells *inter se.*

Normally two fired cartridges can be identified whether they had been fired from the same or different firearms as the marks left by a particular firearm are unique and individual to that firearm. The firearms are not needed to ascertain the factum. The modern NIBIN (Automatic Comparison Systems) does not require firearm(s) for the identification at all. Previously fired cartridge data is used for comparison/evaluation. There is ample support for the proposition in literature: See: Sharma, BR. Firearms in Criminal Investigation and Trials, V Ed.(2017) Pages 252, 263. Only in rare cases, differentiation is not possible when the marks of the firearm are not printed properly or they are mutilated.

Relevant Extracts (Verbatim)

(1) These statutory appeals are filed under section 2(a) of the Supreme Court (Enlargement of Criminal Appellate Jurisdiction) Act, 1970 and under section 379 of the Criminal Procedure Code against the final judgment and order dated 18/20-12-2006 passed by the High Court of Delhi in Criminal Appeal No. 193 of 2006 whereby the High Court reversed the order of acquittal dated 21-2-2006 passed by the Additional Sessions Judge, Delhi, in Sessions Case No. 105 of 2001 and convicted Sidhartha Vashisht @ Manu Sharma (appellant in Crl. A. No. 179 of 2007) under sections 302, 201/120B IPC and section 27 of the Arms Act and sentenced him to undergo imprisonment for life for the offence under section 302 IPC together with a fine of Rs. 50,000 to be paid to the family of the victim and in default of payment of fine, to undergo further imprisonment for three years and also sentenced him to undergo imprisonment for four years for the offence under section 27 of the Arms Act with a fine of Rs. 2000 and in default to further undergo imprisonment for three months. He was further sentenced to undergo imprisonment for four years for the offence under sections 201/120B IPC together with a fine of Rs. 2,000 and, in default, to further undergo imprisonment for three months. The High Court also sentenced Amardeep Singh Gill @ Tony Gill (appellant in Crl. A. No. 157/2007) and Vikas Yadav (appellant in Crl. A. No. 224/2007) to undergo rigorous imprisonment for four years and a fine of Rs. 2000 each and, in default of payment of fine, to further undergo imprisonment for three months under sections 201/120B IPC.

(2) The case of the prosecution:

(a) On night intervening 29/30-4-1999, a 'Thursday Party' was going on at Qutub Colonnade at "Once upon a time" restaurant also called "Tamarind Cafi". The liquor was being served by the bar-tenders, namely, Jessica Lal (since deceased) and one Shyan Munshi (PW-2). At about 2.00 a.m., Sidhartha Vashisht @ Manu Sharma (appellant in Crl. A. No. 179 of 2007) along with his friends came there and asked for two drinks. The waiter did not serve him liquor as the party was over. Jessica Lal and Malini Ramani (PW-6), who were also present there, tried

28. *Manu Sharma v State (NCT of Delhi)*, (2010) 6 SCC 1. (Supreme Court: Criminal Appeal No. 179 of 2007 (with Other appeals); *Sidhartha Vashiht@ Manu Sharma v State (NCT of Delhi),* Judgment: Swatanter Kumar J, decided on 19 April 2010.

to make him understand that the party was over and there was no liquor available with them. On refusal to serve liquor, the appellant took out a pistol and fired one shot at the roof and another at Jessica Lal which hit near her left eye as a result of which she fell down. Beena Ramani (PW-20), who was present there, stopped the appellant and questioned him as to why he had shot Jessica Lal and demanded the weapon from him but he did not hand over the pistol and fled away. Jessica Lal was rushed to Ashlok Hospital from where she was shifted to Apollo Hospital. On 30-4-1999, in the early morning hours, Jessica Lal was declared brought dead at Apollo Hospital.

(b) On the night intervening 29/30-4-1999 at 2.20 a.m., DD Entry No. 41A (Ex. PW-13/A) was recorded at Police Station Mehrauli which disclosed a shooting incident at H-5/6 Qutub Colonnade. A copy of the said DD entry was handed over to SI Sharad Kumar (PW-78) who along with Ct. Meenu Mathew left for the spot. Near about the same time, copy of the said DD entry was also given to SI Sunil Kumar (PW-100) who along with Ct. Subhash also left for the spot. On reaching the spot, PW-78 found that the injured had been removed to Ashlok Hospital and the floor of the Restaurant was found to be wet. SI Sunil Kumar (PW-100) then left SI Sharad Kumar (PW-78) at the spot to guard the same and proceeded to Ashlok Hospital along with Ct. Subhash. The SHO, Police Station Mehrauli, Inspector S.K. Sharma (PW-101) along with his team also left the Police Station *vide* DD Entry No. 43A and reached the spot and deputed one Home Guard Shravan Kumar (PW 30) at the entrance of 'Qutub Colonnade' to guard the vehicles. On reaching Ashlok Hospital, PW-100 met Beena Ramani (PW-20), who is the owner of the Restaurant, and enquired about the incident but she asked him to talk to Shyan Munshi (PW-2) saying that he was inside and he knew everything. PW-100 then recorded the statement of PW-2 and made an endorsement on the same for the registration of the case under section 307 IPC and handed over it to Ct. Subhash to be carried to the police station, Mehrauli. At about 4.00 a.m., FIR No. 287/99 was registered at the police station, Mehrauli. In the meantime, Jessica Lal had been shifted to Apollo Hospital. When SI Sunil Kumar came back to the spot along with PW-2, PW 30 informed them about the lifting of one black Tata Safari from the spot. On inspection of the site, two empty cartridges were seized and, in the meantime, a supplementary statement of PW-2 was also recorded by PW-100. At about 5.45 a.m., PW-100 received an information by Ct. Satyavan intimating him about the death of Jessica Lal at Apollo Hospital. Charge under section 302 IPC/201/120B IPC and under section 27 of the Arms Act has been framed against the accused Sidhartha Vashisht @ Manu Sharma, charge under sections 201/120B IPC has been framed against accused Vikas Yadav, Amardeep Singh Gill @ Tony Gill and Alok Khanna, charge under section 212 IPC has been framed against Harvinder Chopra, Raja Chopra, Vikas Gill @ Ruby Gill and Yograj Singh and charge under sections 201/212 IPC against Shyam Sunder Sharma. At about 7.00 a.m. PW 100 recorded the statement of the Manager (PW-47), Waiter (PW-46) and Beena Ramani (PW-20)-the owner of the Restaurant.

(c) The post-mortem was conducted at about 11.30 a.m. at the All India Institute of Medical Sciences on the same day *i.e.* 30-4-1999. In the meantime, at about 11.00 a.m., SI Pankaj Malik (PW-85) had been sent to Chandigarh to secure the black Tata Safari and to arrest the appellant. PW-100 corded the statements of the witnesses. On 30-4-1999 at about 4.15 p.m., an FIR was registered against Malini Ramani (PW-6), Beena Ramani (PW-20) and George Mailhot (PW-24) under sections 61/68/1/14 of the Punjab Excise Act. At about 8.30 p.m., PW-100 handed over the investigation to SHO S.K. Sharma (PW-101). On the night intervening 30-4-1999/1-5-1999, at about 2 a.m., the police raided the farmhouse of the appellant and on search being conducted seized a photograph of the appellant. On 2-5-1999, a list of invited guests was prepared by PW-24. On the same day, around 10.00 p.m., PW-101, got an information that a black Tata Safari has been found by the U.P. Police (Sector 24, Noida Police Station) and on the next day PW-101 went to Noida Police Station and

seized the said black Tata Safari. On 5-5-1999 at about 2.30 a.m., Amardeep Singh Gill @ Tony Gill and Alok Khanna were arrested and from their alleged disclosure statements, the involvement of Sidhartha Vashisht @ Manu Sharma was confirmed. On the same day, Inspector Raman Lamba (PW 87) who was in Chandigarh with his team intimated the lawyer of the accused-appellant that Manu Sharma is required in the case. On receipt of the information, on 6-5-1999, the appellant surrendered before PW-87 and was later arrested at about 2.20 p.m. and brought to Delhi. On 7-5-1999, the police produced the appellant before the Metropolitan Magistrate and sought police remand for effecting recovery of the alleged weapon of offence. An application for conducting Test Identification Parade (TIP) of the appellant was also moved. Thereafter, the appellant was remanded to five days police custody till 12-5-1999 and thereafter on 12-5-1999 extended till 17-5-1999 on the application of the I.O., but on 15-5-1999, the appellant's remand was preponed from 17-5-1999 to 15-5-1999. On 16-5-1999, the appellant was sent to judicial custody. On 30-5-1999, the accused-Vikas Yadav was also arrested. After the completion of the investigation, the other accused persons were also arrested.

(d) On 3-8-1999, charge-sheet was filed against ten accused persons. On 23-11-2000, the Additional Sessions Judge framed charges against the appellant/Manu Sharma under sections 302, 201 read with section 120B IPC and section 27 of the Arms Act, accused Amardeep Singh Gill was charged under section 120 read with section 201 IPC, accused Vikas Yadav was charged under section 120 read with section 201 IPC as also section 201 read with 34 IPC, accused Harvinder Chopra, Vikas Gill, Yograj Singh and Raja Chopra under section 212 IPC and accused Alok Khanna, Shyam Sunder Sharma and Amit Jhingan were discharged of all the offences. In 2000/2001, Revision Petition No. 596 of 2000 was preferred by the prosecution before the High Court of Delhi praying for the framing of charge against the accused persons and setting aside the discharge of Alok Khanna, Shyam Sunder Sharma and Amit Jhingan. Revision Petitions were also preferred by the accused persons against the framing of the charges against them. The High Court disposed of all the revision petitions filed by the accused persons by a common order dated 13-3-2001. On 12-4-2001, charges as per the orders of the High Court were framed and some of the charges as framed earlier were maintained. Charges under sections 120B/201 IPC were framed against accused Vikas Yadav, Amardeep Singh Gill @ Tony Gill and Alok Khanna and charges under sections 201 and 212 IPC were framed against accused Shyam Sunder Sharma. Against the rest of the accused, the charges as framed on 23-11-2000 by the trial court were maintained. Trial began in May, 2001 against nine accused. In all, 101 witnesses were examined by the prosecution and two court witnesses were also examined.

(e) …….On 28-1-2002, the appellant was released on interim bail for a period of six weeks by the order of the High Court dated 25-1-2002 with a direction to surrender after the expiry of the same. In compliance with the conditions of interim bail, the appellant surrendered on 11-3-2002 but again sought for and granted interim bail for a period of ten weeks starting from 20-3-2002. During the period from March 2002 to February 2006, the appellant was enlarged on bail on different occasions by various orders of the High Court. On one occasion, against the dismissal of the bail application by the High Court on 11-11-2003, the appellant filed a special leave petition before this Court which was dismissed by this Court on 2-12-2003. On 21-2-2006, after trial, the Additional Sessions Judge acquitted all the nine accused including the appellant-Manu Sharma.

(f) Challenging the acquittal, the prosecution filed an appeal before the High Court, being Crl. Appeal No. 193 of 2006. On 20-12-2006, the High Court *vide* the impugned order, convicted and sentenced the appellants, as mentioned in paragraphs above. Challenging the said order of the High Court, all the three appellants filed above mentioned separate appeals before this Court. All the appeals were heard together and are being disposed of by this common judgment.

(64) The evidence in respect of two FSL reports is as under:

By letter dated 6-7-1999, the seized material was forwarded to CFSL for examination and expert opinion and, *inter alia*, the following queries were made to be opined by the CFSL:

"5. Please examine and opine whether the two empties present in parcel mentioned at SI. No. 5 have been fired from the same weapon?

6. Please examine and opine whether the bullet lead in parcel No. 6 and the bullet empties in parcel No. 5 have been fired from a standard firearm or a country made firearm?

7. Please examine and opine whether ejector, trigger, chamber, magazine or other chamber marks are present on the live bullet empties contained in parcel Nos. 6 & 5 respectively?

8. If the answer to query No. 7 is yes them whether these marks are similar and caused by the same firearm?"

The Ballistics Division of CFSL gave report in respect of the queries as under:

"(1) The .22 badly mutilated lead bullet (marked BC/1) of No. 3 could have been fired from a standard .22 caliber firearm.

(2) The two .22 cartridge cases marked C/l and C/2 have been fired from two different .22 caliber standard firearms.

(3) The .22 cartridge (marked C/3) of parcel No. 5 is a live cartridge and no characteristic tool marks (*i.e.* firing pin, ejector, extractor, breech face, magazine or chamber marks etc.) could be observed on this cartridge.

(4) The two .22 cartridge cases (marked C/l & C/2) of parcel No. 4 and the .22 cartridge (marked C/3) of parcel No. 5 have similar Head Stamp of 'C' indicating that they are of the same make. No opinion on their series (lot/batch) could however be given."

According to the State the same also contained inconclusive opinion. It was pointed out that the State has neither relied on the report of the expert Sh. Rup Singh nor had filed it in the trial Court. An application was moved by the accused for the supply of the document and *vide* order dated 14-1-2000, the Metropolitan Magistrate directed that the State will have to supply all the deficient copies and also the remaining CFSL reports sent by CFSL to SHO. The opinion of Sh. Rup Singh, Ballistic expert finally exhibited as Ex. PW 89/DB only says that "it appears that the two cartridge cases are from two different pistols." As rightly pointed out such a vague opinion of the expert can neither be relied upon nor can be any basis to come to a conclusion that there were two persons who had fired two different shots.

(65) With regard to Prem Sagar Manocha PW-95, Ballistic expert at FSL, Jaipur, a specific query being query No. 3 that whether both the empty cartridge cases have been fired from the same firearm or otherwise. In the reply to the said query, the expert opined that no definite opinion could be given on the two .22 bore cartridge cases C-l and C-2 in order to link with the firearm unless the suspected firearm is available to examination.

It was pointed out that the trial court puts a question to the witness and while putting the question first gives a specific fact finding that for reply to Query No. 3, the presence of the firearm was not necessary. This incorrect finding of fact given by the trial court based on no expertise and had resulted in grave miscarriage of justice.

It is well-settled that while giving reports after Ballistic examination, the bullets, cartridge case and the cartridges recovered and weapon of offence recovered are carefully examined and test firing is done at the FSL by the said weapon of offence and then only a specific opinion is given.

(66) It is contended by the learned counsel for the appellant/Manu Sharma that the prosecution tried their level best to suppress the report of the Ballistic expert Shri Rup Singh

which was not favourable to them and that the same was exhibited at the instance of the defence as Ex. PW 89/DB. It has been further argued that while the charge-sheet was filed on 3-8-1999, the police sought an expert opinion practically at the end of the investigation *i.e. vide* letter dated 16-7-1999, Ex. PW-89/DA. At Sl. No. 67 of the charge sheet one finds mention of the letters sent by the SHO seeking the expert opinion. The charge sheet was filed without expert opinion. The accused on seeing Sl. No. 67, approached the committal Court and asked for the expert report. It has been argued that the I.O. had received the opinion in the first week of December, 1999 but did not file the same. On 21-12-1999, the Court directed the prosecution to file the report. The SPP objected to the same on the ground that the order required modification but the same was rejected and on 14-1-2000, the Court again directed supply of the expert report. It has been argued that since the report did not favour the prosecution, the same was withheld. It has been further argued by the defence that failure on the part of the prosecution to bring on record material which is in favour of the accused is a breach of article 21 of the Constitution. It has been argued by the defence that it was improper on the part of the prosecution to condemn a ballistic expert, *i.e.,* Rup Singh without calling him in for cross-examination. It has been further argued by the defence that by virtue of section 293 Cr.P.C, the report is admissible in evidence and that the weapon is not required to show whether the two empties are fired from the same gun and the weapon is only required when one has to determine as to whether a particular weapon was responsible for firing the empties in question. The expert evidence is only good if it appeals to the judicial lines; appreciation of such evidence can only be the work of the Court. Reliance has been placed on *A.E.G. Carapiet v A.Y. Derderian*, AIR 1961 Cal 359 paras 10-14 to assert that every witness must be cross-examined before being discredited. The prosecution cannot challenge the expert at the stage of appeal when his testimony went unchallenged at the stage of the trial.

(67) It has been argued that the Court must lay down in clear terms the duties of a public prosecutor *i.e.*, to tell the truth even if the same is in favour of the accused. Reliance has been placed on rule 16 of the Bar Council of India Rules which are to the said effect. Reliance is further placed on Attorney-Generals Guidelines contained in Archbold Criminal pleadings edition 2003 to say that it is obligatory on the part of the prosecution to disclose all the material. It has been argued that even after an application under section 391 Cr.P.C. has been filed, the prosecution still chose not to call the expert Rup Singh and cross-examine him. Ex. PW-89/DB supports PW-2 and *vice versa*, since his evidence is corroborated by the expert report. The attention of the Court was invited to the results of the examination. As regards the 2nd opinion given by PW-95, it has been argued that this court must assume that the prosecution sought a favourable opinion from the said witness. The said witness obliged them and created confusion by saying that no conclusive opinion can be given without examining the weapon in question.

(67) It was pointed out by the State that the said report of Rup Singh is inadmissible in law since it is a photocopy and, therefore, does not fall within the purview of a report in terms of section 293 of the Code. In other words, in terms of the relevant provisions of the Indian Evidence Act unless the original document is placed for the scrutiny of the Court, no reliance can be placed on the photocopy without leading proper secondary evidence in this regard. In any case, both section 293 and section 294 of the Code which dispense with a formal proof of documents under certain circumstances make it abundantly clear that the documents sought to be relied upon must be the originals.

1. Assuming for the sake of the argument, though not admitting, that the said report of Rup Singh, *i.e.,* Ex. PW-89/DB is admissible even though a photocopy has been placed on record and even though nowhere it has come in evidence that the same *i.e.,* the photocopy has been compared and scrutinized with the original by the Court and then placed on record, the same still loses all credence in the light of the fact that a perusal of the forwarding letter and report would show that there seems to have been some tampering with the said documents since the sequence of numbering of the parcels as between the forwarding letter and the report has been changed by somebody which fact remains unexplained as, therefore, casts a

further doubt on the genuineness of the said report. The report itself with regard to query No. 3 shows that "it appears that the two cartridge cases C-l and C-2 have been fired by two different weapons". This opinion of the expert was vague and on the basis of said opinion no credence can be lent to the fact adverted to by the defence that there were two persons who fired two different shots from two different weapons.

Moreover the said report is oddly silent on query No. 7 of the forwarding letter wherein it was specifically asked about the various markings on the live cartridge and the bullet empties. The stand of the defence that to opine the two cartridge cases are from the same weapon or not the pistol is not required and the pistol is only required when the opinion is sought whether they are from that particular weapon or not cannot be accepted. It is well-settled that when pressure is built inside the cartridge case, which results in the pushing out of the bullet from the barrel, there is difference in the marks to the extent that it may be either clear or unclear and flattened or deepened thus no opinion can be rendered on account of this dissimilarity in the absence of the weapon of offence and test firing.

Further once the report of Rup Singh is rendered inadmissible the two-gun theory of the defence becomes wholly inadmissible and what remains is that the two empties found at the spot are .22 bore cartridges, that the live bullet found in the Tata Safari is a .22 cartridge and that the gun belonging to the appellant is a .22 bore pistol which was used for the commission of the crime of murder of Jessica Lal.

(68) The prosecution obtained another opinion from FSL Rajasthan and the queries made are as under:

"1. Please examine and opine the bore of the two empty cartridges present in the sealed parcel.

2. Please opine whether these two empty cartridges have been fired from a pistol or a revolver.

3. Whether both the empty cartridges have been fired from the same firearm or otherwise."

In response to these queries, the expert opinion of the FSL, Rajasthan is as under:

"1. The caliber of two cartridge cases (C/l and C/2) is .24.

2. These two cartridge cases (C/1 and C/2) appear to have been fired from a pistol.

3. No definite opinion could be given on two .22 cartridge cases (C/1 and C/2) in order to link with firearm unless the suspected firearm is available for examination."

It was pointed out by the State that this opinion also was inconclusive in nature. In the worksheet, it was categorically recorded that the Investigating Officer be informed to make available the suspected firearm used for a definite opinion on linking of C-1 and C-2 with the same firearm or otherwise. The worksheet also records that the firearm involved be sent for definite opinion. At this juncture, it is relevant to note that the trial court posed a leading question as under:

"**Q**. From reply to query No. 3 the presence of the firearm was not necessary. The question was whether the two empty cartridges have been fired from one instrument or from different instruments?

Ans. The question is now clear to me. I can answer the query here and now these two cartridge cases were examined physically and under sterio and comparison microscope to study and observe and compare the evidence and the characteristics marks present on them which have been printed during firing. After comparison, I am of the opinion that these two cartridge cases C/1 and C/2 appeared to have been fired from two different firearms."

The said witness in further cross-examination replied as under:

"There is nothing in the record of the Court on my report on the basis of which I had given this finding that C/1 and C/2 were fired from two different firearms"

The said witness in further cross-examination deposes that no photographs were taken or there is any other evidence to show the basis of opinion given by the witness before the trial court.

(69) The learned senior counsel for the appellant-accused has contended that the contention of the prosecution that the trial court could not have asked the particular Court question to PW-95 is contrary to section 165 Cr.P.C. inasmuch as the power of Judge is very wide. It has been further argued by the defence that the duties of a Presiding Officer are set out in section 165 of the Indian Evidence Act. Reliance is sought to be placed on *Ram Chander v State of Haryana*, AIR 1981 SC 1036 : 1981 Cr LJ 609 : (1981) 3 SCC 191. It has been argued that the judge knew that the issue was whether two empties were fired from the same gun. It has been further argued that the judge has seen Ex. PW-89/DB and, therefore, any judge would have noticed that the controversy was whether these two bullets were fired from the same weapon or not. The judge also found out that this query went to the CFSL and CFSL answered the same. It has been argued that, therefore, the Judge knew that to answer this query weapon was not required. It has been argued that the Court must read in between the lines.

(70) It is pointed out by the State that the contention of the prosecution was that the trial court could not have first put a specific finding of its own opinion to the expert witness and then to ask him questions. Learned Solicitor-General pointed out that in the attempt of the trial court to extract the truth from the said witness, it misdirected itself in law by posing such a question. This is impermissible even as per the judgment in *Ram Chander* (supra) relied on by the defence. This judgment is in fact in favour of the prosecution since the same clearly puts an embargo on the power of a judge to ask questions so as to frighten, coerce, confuse or intimidate the witness. The danger inherent in a judge adopting a much too stern an attitude towards witness has been duly explained in the said decision. The judge cannot ask questions which may confuse a witness. The argument that the judge knew that the issue in question was whether the two empties found on the spot were fired from the same gun is wrong and misleading. The judge knew that as per the charge framed against Manu Sharma it was he alone who was charged with the possession and use of a gun. The judge also knew that the first expert opinion was brought on record at the instance of the accused; the judge further knew that PW-95 had stated in no uncertain terms that no opinion can be given as regards the two empties without receipt of the weapon of offence.

In spite of knowing all this, the judge first put a finding of its own to the witness that he did not need the firearm in question in order to reply as to whether the two empties were fired from the same gun* i.e., *a gun and not the gun. The Court exceeded its power under section 165 of the Evidence Act by putting the question after giving its own finding.

(71) On behalf of the prosecution, it is pointed out that the entire argument of the accused that an expert opinion was sought at the fag end of the charge sheet to seek a favourable opinion in favour of the prosecution in fact suggests that the I.O. in question was oblivious of the fact that such an opinion could work to the detriment of the case of the prosecution *i.e.,* two empties having been fired from the same weapon of offence belonging to accused Manu Sharma. The fact that the I.O. sought to mention at S. No. 67 of the list of documents in the charge-sheet about the forwarding letter to the expert only suggests that the prosecution had no intention of carrying out the act of seeking an expert opinion, is hiding.

The discretion on the part of the I.O. and the superior officers was rightly exercised when they decided not to file the expert report since they realized that the expert report is ambiguous as it uses the term "appear" when it suggests that the two empties appear to have been fired from different weapons. Clearly the said opinion was far from conclusive and would have only created confusion in the case of the prosecution.

Thereafter a second opinion was sought wherein the expert *i.e.*, PW-95 opined that a conclusive opinion can only be given after the receipt of the weapon of offence. The argument that the weapon of offence is not required to determine whether the two bullets have been fired from the same gun is based on the wrong premise that the two empties would necessarily consist of features which would enable an expert in determining the said fact. For instance, as in the case of a handwriting expert who has to give an opinion about two different sets of near identical questioned documents and as to whether the same belong to different persons, if the argument of the accused has to be accepted then the expert should be able to give such an opinion without having in his possession the specimen handwriting and the admitted handwriting of the accused. It is stated that such an approach would render the opinion as that of a layman and not an expert. Similar would be case of a finger print expert who undertakes the process of discovering two different sets of finger print which are in question, without having the specimen or the admitted finger print of the accused in question. In other words,

an expert is only an expert if he follows the well accepted guidelines to arrive at a conclusion and supports the same with logical reasoning which is a requirement of law as laid down in the Indian Evidence Act. In the present case, the moment Rup Singh uses the word "appear" his opinion unsupported by reasons becomes inconclusive and stands discredited for the purpose of placing reliance on. The opinion of Rup Singh was at query No. 7 as to "please examine and opine whether ejector, trigger, chamber, magazine or other tool marks are present on the live bullet and the bullet empties contained in parcel Nos. 6 & 5 respectively."

Though Shri Rup Singh has given opinion qua query No. 5 that the two .22 cartridge cases appears to have been fired from two different .22 caliber standard firearms but his opinion is completely silent on the marks i.e. ejector, trigger, chamber, magazine or other tool marks on the bullet empties (Ex. PW 89/DB). Clearly an option was available to the accused under section 293 Cr.P.C. to call for the witness and ascertain from his for sure that the two empties were in fact fire from two different weapons, however, the accused did not choose to do so in terms of section 293 Cr.P.C. In any case, the opinion of Rup Singh as of today is of little use to the accused for the reasons stated above and since it is both inconclusive and unsupported by any reasoning whatsoever and, therefore, cannot appeal to the judicial mind of this Court. Similar is the case with the expert opinion of PW-95 which is again inconclusive. There is no evidence on record to suggest that PW-95 gave an opinion to oblige the prosecution. On the contrary, his response to the Court question reveals that he was extremely confused as to the issue which had to be addressed by him in the capacity of an expert. In the concluding part of his testimony he reaffirms the opinion given by him which is that without test firing the empties from the weapon of offence no conclusive opinion can be given.

72. It is pertinent to note that the testimony of the experts i.e., Rup Singh exhibited as Ex. PW-89/DB and PW-95 Prem Sagar Minocha exhibited as Ex. PW-95/C-1 in inconclusive. The expert PW-95 Prem Sagar Minocha has stated in his report that it is only on receiving the weapon of offence that a conclusive opinion as to whether the two empties (cartridge cases) found at the spot were fired from the same weapon or from two different weapons could be given.

73. The defence seeks to reply upon the testimony of PW-2 with regard to the two-gun theory put forward. In this regard, the defence seeks to corroborate the said part of PW-2's testimony with the testimony of the two ballistic experts. It has also been contended by the defence that the testimony of a hostile witness must be corroborated by the other reliable evidence on record in order to be admissible. The law is very clear that where a witness for the prosecution turns hostile, the Court may rely upon so much of the testimony, which supports the case of the prosecution and is corroborated by other evidence. PW-2's testimony as regards the identity of the person shooting, is certainly not corroborated by the testimony of the experts since both the experts have given opinions which cannot qualify as the conclusive opinion of experts.

37.17 HANDWRITING IDENTIFICATION AT PAR WITH OTHER EXPERTISE[29]

Author's Summary

It is a judgment that should put the evaluation of Handwriting on an even keel. The SC had been writing so much against the Science that it created a conformational Syndrome in the minds of judiciary. The judgment in this case took the cudgel to set the record of the expertise straight. It is a well-argued judgment and the judiciary has started rethinking about the condemnation. Another judgment (next case) the Sc has followed the line delineated in this case. It is true that SC had accepted and utilised the expertise; however only after showing expressing solidarity with the numerous condemnations**.**

Relevant Extract

1. *An expert is no accomplice. There is no justification for condemning the opinion-evidence of an expert to the same class of evidence as that of an accomplice and insist upon corroboration.* The view occasionally expressed that it would be hazardous to base a conviction solely on the opinion of an expert-handwriting expert or any other kind of expert-without substantial corroboration is not, because experts in general, are unreliable witnesses, but because all human judgment is fallible. The more developed and the more perfect a science, the less the chance of an incorrect opinion. The science of identification of handwriting, unlike the science of identification of fingerprints which has attained near-perfection is not quite perfect and the risk is, therefore, higher.

But that is a far cry from doubting the opinion of a handwriting expert as an invariable rule and insisting upon substantial corroboration in every case, howsoever the opinion may be backed by the soundest of reasons.

An expert opinion has to be tested by the acceptability of the reasons given by him. An expert deposes and not decides. His duty is to furnish the judge with the necessary scientific criteria for testing the accuracy of his conclusion so as to enable the judge to form his own independent judgment by the application of these criteria to the facts proved in evidence.

2. *There is no rule of law nor any rule of prudence which has crystallized into a rule of law that opinion evidence of a hand-writing expert must never be acted upon unless substantially corroborated. But having due regard to the imperfect nature of the science of identification of handwriting, the approach should be one of caution. Reasons for the opinion must be carefully probed and examined. All other relevant evidence must be considered.*

In appropriate cases, corroboration may be sought. In cases where the reasons for the opinion are convincing and there is no reliable evidence throwing a doubt, the uncorroborated testimony of a handwriting expert may be accepted. There cannot be an inflexible rule on a matter which, in the ultimate analysis, is no more than a question of testimonial weight.

3. Section 73 of Evidence Act expressly enables the court to compare disputed writings with admitted or proved writings to ascertain whether a writing is that of the person by whom it purports to have been written. If it is hazardous to do so, it is one of the hazards to which a judge and litigant must expose themselves whenever it becomes necessary. In cases where both sides call experts it becomes the plain duty of the court to compare the writings and come to its own conclusion. Where there are expert opinions, they will aid the Court. Where there is none the Court will have to seek guidance from some authoritative text book and the Court's own experience and knowledge.

[*Ram Chander v U.P. State,* AIR 1957 SC.; Ishwari Prasad Misra v Mohammed Isa, [1963] 3, S.C.R. 722; Shashi Kumar v Subhodh Kumar,AIR 1964 SC 529; *Fakhruddin*

29. *Murarilal v State of Madhya Pradesh*, AIR 1980 SC 531 : (1980) 1 SCC 704 : 1980 Cr LJ 396.

v State of Madhya Pradesh, AIR. 1967 SC 1326 : (1967) Cr LJ 1197; Magan Bihari Lal v State of Punjab, AIR 1977 SC 1091, referred to.]

In the instant case the courts below compared the disputed handwriting with the admitted writing of the appellant and found, in conjunction with the opinion of the expert, that the author of the note was the same person. The appellant was not able to say a word against the reasons given by the expert. (b) The note was designed to lay a false trail by making it appear that the murder and the robbery were the handiwork of some frustrated and unemployed graduates expressing their resentment against the world which had shown no regard for their existence.

(c) Had the recovery of the wrist watch of the deceased in February, 1973 at the instance of the appellant been the only circumstance it would have been difficult to link it with the murder which took place ten months earlier in April, 1972. But there is the vital circumstance that a writing made by the appellant was found on the table by the side of the deceased on the day of occurrence. This circumstance, coupled with the recovery of the dead man's watch, was sufficient to hold him guilty of the offence of which he had man's convicted.

37.18 HANDWRITING IDENTIFICATION EVIDENCE ADMISSIBLE[30] (AT PAR WITH OTHER SCIENTIFIC EVIDENCE)

Author's Summary

It is a case of forgery of railway receipt by an employee of the railways; by which consignment was diverted from its destination and contents usurped.

Document expert identified the handwriting of the forger. The three courts, including the SC accepted the expert opinion of the handwriting expert, reiterating that the handwriting expert's opinion alone can be sufficient for conviction , provided it is properly appraised. The culprit was convicted.

Relevant Extracts (Verbatim)

In the first place, it may be noted that the appellant was at the material time a Guard in the employment of the Railway Administration with his headquarters at Agra and he had nothing to do with the train by which Wagon No. SEKG 40765 was dispatched from Munda to Bikaner, nor with the train, which carried that wagon from Agra to Ludhiana. He was not a Guard on either of these two trains. There was also no evidence to connect the appellant with the theft of the blank Railway Receipt at Banmore Station. It is indeed difficult to see how the appellant, who was a small employee in the Railway Administration, could have possibly come into possession of the blank Railway Receipt from Banmore Station which was not within his jurisdiction at any time. It is true that B. Lal, the Handwriting Expert, deposed that the handwriting on the forged Railway Receipt Ex. PW-10/A was that of the same person who wrote the specimen handwritings, Ex. PW-27/37/ to 27/57, that is the appellant, but we think it would be extremely hazardous to condemn the appellant merely on the strength of opinion evidence of a Handwriting Expert. It is now well-settled that Expert opinion must always be received with great caution and perhaps none so with more caution than the opinion of a Handwriting Expert. There is a profusion of precedential authority which holds that it is unsafe to base a conviction solely on Expert opinion without substantial corroboration. This rule has been universally acted upon and it has almost become a rule of law. It was held by this Court in *Ram Chandra v State of Uttar Pradesh*, AIR 1957 SC 381 : 1957 Cr LJ 559, that it is unsafe to treat Expert Handwriting

30. *Alamgir v State (NCT, Delhi)*, AIR 2003 SC 282 : 2002 AIR SCW 4749 : 2003 Cr LJ 456 (SC).

opinion as sufficient basis for conviction, but it may be relied upon when supported by other items of internal and external evidence. This Court again pointed out in *Ishwari Prasad Misra v Mohammad Isa*, AIR 1963 SC 1728 : 1963 BLJR 226 : (1963) 2 SCR 722, that Expert evidence of handwriting can never be conclusive because it is, after all, opinion evidence, and this view was reiterated in *Shashi Kumar Banerjee v Subodh Kumar Banerjee*, AIR 1964 SC 529, where it was pointed out by this Court that Expert evidence as to handwriting being opinion evidence can rarely, if ever, take the place of substantive evidence and before acting on such evidence, it would be desirable to consider whether it is corroborated either by clear direct evidence or by circumstantial evidence. This Court had again occasion to consider the evidentiary value of Expert opinion in regard to handwriting in *Fakhruddin v State of Madhya Pradesh,* AIR 1967 SC 1326 : (1967) 1 SCWR 449 : 1967 Cr LJ 1197, and it uttered a note of caution pointing out that it would be risky to found a conviction solely on the evidence of a handwriting expert and before acting upon such evidence, the Court must always try to see whether it is corroborated by other evidence direct or circumstantial. It is interesting to note that the same view is also echoed in the Judgments of English and American Courts, Vide *Gurney v Langlands*, 1822 (5) B and Ald 330, and Matter of Alfred Foster's Will (34 Mich 21). The Supreme Court of Michigan pointed out in the last mentioned case.

Everyone knows how very unsafe it is to rely upon any one's opinion considering the niceties of penmanship – Opinions are necessarily received, and may be valuable, but at best this kind of evidence is a necessary evil.

We need not subscribe to the extreme view expressed by the Supreme Court of Michigan, but there can be no doubt that this type of evidence, being opinion evidence is by its very nature, weak and infirm and cannot of itself form the basis for a conviction. We must, therefore, try to see whether, in the present case, there is, apart from the evidence of the Handwriting Expert B. Lal, any other evidence connecting the appellant with the offence.

In our view, however, reliance in Magan (supra) is rather misplaced in the contextual facts since no conviction is based on the opinion of the Handwriting Expert but admittedly it can be relied upon when supported by other items of internal and external evidence. The Handwriting Expert's opinion simply corroborates the circumstantial evidence and as such we are unable to record our concurrence with the submissions of Mr. Singh on this score.

Significantly, this Court in Murarilal v State of Madhya Pradesh, AIR 1980 SC 531: (1980) 1 SCC 704: 1980 Cr LJ 396, in no uncertain terms observed that the hazard in acceptance of opinion of an Expert is not because it is unreliable evidence, but because human judgment is fallible. Needless to record that the signs of identification of handwriting have attained more or less a state of perfection and the risk of an incorrect opinion is practically non-existent. This Court went on further to record that doubting the opinion of a Handwriting Expert ought to be a far cry and insistence upon further corroboration as an invariable rule does not seem to be a justifiable conclusion.

In continuation of the above-noted principle, this Court went on to further examine as regards judicial precedence and in that vein stated in paragraph 7 of the report as below:

> *"7. Apart from principle, let us examine if precedents justify in variable insistence on corroboration. We have referred to* Phipson on Evidence, Cross on Evidence, Roscoe on Criminal Evidence, Archibald on Criminal Pleadings, Evidence and Practice and Halsbury's Laws of England *but we were unable to find a single sentence hinting at such a rule. We may now refer to some of the decisions of this Court. In Ram Chandra v State of Uttar Pradesh*, AIR 1957 SC 381 : 1957 Cr LJ 559, *Jagannadhadas, J. observed: "It may be that normally it is not safe to treat Expert evidence as to handwriting as sufficient basis for conviction". "May" and "normally" make our point about the absence of an inflexible rule. In* Ishwari *Prasad Misra v Mohammad Isa*, AIR 1963 SC 1728 : 1963 BLJR 226 : (1963) 2 SCR 722, *Gajendragadkar, J. observed;*

"Evidence given by Experts can never be conclusive, because after all it is opinion-evidence", a statement which carries us nowhere on the question now, under consideration. Nor, can the

statement be disputed because it is not so provided by the Evidence Act and, on the contrary, section 46 expressly makes opinion-evidence challengeable by facts, otherwise irrelevant. And as Lord President Cooper observed in Davis v Edinburgh Magistrate, *AIR 1953 SC 34: "The parties have invoked the decision of a judicial tribunal and not an oracular pronouncement by an Expert."*

As regards the decision of *Magan* (supra) this Court in paragraph (10) stated as below:

"10. Finally, we come to *Magan Bihari Lal* v *State of Punjab*, AIR 1977 SC 1091 : 1977 Cr LJ 711 : (1977) 2 SCC 210, upon which Sri R.C. Kohli, learned counsel, placed great reliance. It was said by this Court:

……but we think it would be extremely hazardous to condemn the appellant merely on the strength of opinion evidence of a Handwriting Expert. It is now well-settled that Expert opinion must always be received with great caution and perhaps none so with more caution than the opinion of a Handwriting Expert. There is a profusion of precedential authority which holds that it is unsafe to base a conviction solely on Expert opinion without substantial corroboration. This rule has been universally acted upon and it has almost become a rule of law.

It was held by this Court in *Ram Chandra v State of Uttar Pradesh*, AIR 1957 SC 381 : 1957 Cr LJ 559, that it is unsafe to treat Expert Handwriting opinion as sufficient basis for conviction, but it may be relied upon when supported by other items of internal and external evidence. This Court again pointed out in *Ishwari Prasad Misra v Mohammad Isa*, AIR 1963 SC 1728 : 1963 BLJR 226 : (1963) 2 SCR 722, that Expert evidence of handwriting can never be conclusive because it is, after all, opinion-evidence, and this view was reiterated in *Shashi Kumar Banerjee v Subodh Kumar Banerjee*, AIR 1964 SC 529, where it was pointed out by this Court that Expert evidence as to handwriting being opinion-evidence can rarely, if ever, take the place of substantive evidence and before acting on such evidence, it would be desirable to consider whether it is corroborated either by clear direct evidence or by circumstantial evidence. This Court had again occasion to consider the evidentiary value of Expert opinion in regard to handwriting in *Fakhruddin v State of Madhya Pradesh,* AIR 1967 SC 1326 : (1967) 1 SCWR 449 : 1967 Cr LJ 1197, and it uttered a note of caution pointing out that it would be risky to found a conviction solely on the evidence of a Handwriting Expert and before acting upon such evidence, the Court must always try to see whether it is corroborated by other evidence, direct or circumstantial.

The above extracted passage, undoubtedly, contains some sweeping general observations. But we do not think that the observations were meant to be observations of general application or as laying down any legal principle. It was plainly intended to be a rule of caution and not a rule of law as is clear from the statement "it has almost become a rule of law". "Almost", we presume, means, "not quite". It was said by the Court there was a "profusion of precedential authority" which insisted upon corroboration and reference was made to Ram Chandra v State of Uttar Pardesh; Isdhwari Prasad v Mohammad Isa; Shashi Kumar v Subodh Kumar and Fakhruddin v State of Madhya Pradesh. We have already discussed these cases and observed that none of them supports the proposition that corroboration must invariably be sought before opinion-evidence can be accepted. There appears to be some mistake in the last sentence of the above extracted passage because we are unable to find in Fakhruddin v State of Madhya Pradesh, any statement such as the one attributed. In fact, in that case, the learned judges acted upon the sole testimony of the Expert after satisfying themselves about the correctness of the opinion by comparing the writings themselves. We do think that the observations in Magan Bihari Lal v State of Punjab, must be understood as referring to the facts of the particular case."

In fine, in *Murarilal* (supra) this Court stated that there is no rule of law, nor any rule of prudence which has crystallised into a rule of law that opinion evidence of a Handwriting Expert must never be acted upon, unless substantially corroborated.

We feel it expedient to record our concurrence therewith, though, however, we hasten to add that since human judgment cannot be said to be totally infallible, due caution

shall have to be exercised and the approach ought to be that of care and caution and it is only upon probe and examination the acceptability or creditworthy of the same depends. The learned Sessions Judge, as also the High Court, did place upon consideration of all relevant facts and material on record, reliance on the opinion of the Handwriting Expert and we do not see any reason to record a contra finding.

37.19 SPECIMENS u/s 73, IEA[31,32]

Author's Summary

It is a simple case of interpreting the power of the court u/s 73 of the IEA. The SC ruled that the court has no powers to order any person to give specimen writing in cases under investigation. However, during trials if the court needs specimens for its own scrutiny, it have the powers to order**.** Addition of Section 311 A in Cr P C has, now, given powers to order specimens during investigation.

Highlights italicised

Relevant Extracts (Verbatim)

We shall examine the circumstances highlighted. So far as ransom notes are concerned, prosecution sought to rely upon the report given by the handwriting expert. It appears that the accused was taken before Addl. Chief Judicial Magistrate, Bhiwani. According to him, on 10-9-1991 the accused was brought before him in custody for giving his specimen signature under section 73 of the Evidence Act. It was noticed by this Court in *State of Uttar Pradesh v Ram Babu Misra*, AIR 1980 SC 791 that the Chief Judicial Magistrate has no power to direct the accused to give his specimen signature for comparison during the investigation. Section 73 of the Evidence Act reads as follows:

> *"Section 73—Comparison of signature, writing or seal with others admitted or proved:* In order to ascertain whether a signature, writing, or seal is that of the person by whom it purports to have been written or made, any signature, writing, or seal admitted or proved to the satisfaction of the Court to have been written or made by that person may be compared with the one which is to be proved, although that signature, writing, or seal has not been produced or proved for any other purpose.

The Court may direct any person present in Court to write any words or figures for the purpose of enabling the Court to compare the words or figures so written with any words or figures alleged to have been written by such person.

This section also applies, with any necessary modifications, to finger-impressions".

The second paragraph of section 73 enables the Court to direct any person present in the Court to give specimen writings 'for the purpose of enabling the Court to compare' such writings with writings alleged to have been written by such person.

The clear implication of the words for the purpose of enabling the Court to compare' is that there is some proceeding before the Court in which or as a consequence of which it might be necessary for the Court to compare such writings. The direction is to be given for the purpose of enabling the Court to compare and not for the purpose of enabling the investigating or other agency 'to compare'. If the case is still under investigation there is no present proceeding before the Court in which or as a consequence of which it might be necessary to compare the writings. The language of section 73 does not permit a Court to give a direction to the accused to give specimen writings for anticipated necessity for comparison in a proceeding which may later be instituted in the Court.

31. *State of Haryana v Jagbir Singh*, AIR 2003 SC 4377 : 2003 AIR SCW 5180 : 003 Cr LJ 5054 (SC).
32. The judgment brought Amendment to the law. Section 311A was added to the Code of Criminal Procedure.

37.20 HANDWRITING REPORTS u/s 293 CRPC[33]

Author's Summary

In this case, the report of a handwriting expert was accepted by the appellate court u/s 293 of Cr P C. The expert was not examined. The defence stressed that the report of the expert, without his deposition, is no evidence. The SC agreed with the defence as the document expert is not one of the specified experts in Section 293 of Cr PC . and order to call the expert to prove his report, with opportunity to defence for cross-examination.

Highlights italicised

Relevant Extracts (Verbatim)

Reports of Document Expert not covered under section 293 CrPC

Mr. Singh, learned Counsel for the petitioner submitted that the petitioner has been found guilty solely on the basis of the report of the Government Examiner of Questioned Documents, Exhibit 29, but the expert who submitted the said report was not examined and his report was proved by the Investigating Officer which is not permissible. By referring to sub-section (4) of section293, CrPC, he submitted that report of those government scientific experts mentioned therein can be admitted into evidence without they being examined, but in the instant case the handwriting expert was the Deputy Government Examiner and the said expert is not one of the experts mentioned in sub-section (4) of section 293, CrPC Mr. Pradhan, learned Additional Public Prosecutor, on the other hand, submitted that the conviction of the petitioner is not based solely on the report of the handwriting expert. There is also other evidence on record which justifies his conviction.

I have perused the impugned judgment and on its close scrutiny it appears that the learned Sessions Judge has not discussed the evidence on record at all. In paragraph 7 of the judgment he has referred to the arguments of the Public Prosecutor who seems to have submitted before him that for different offences committed by the petitioner, there is evidence of certain PWs and separate documentary evidence.

It may be stated that as an appellate Court, the learned Sessions Judge is required to assess and consider the evidence on record independently. As a court of appeal, he has to remember and keep in view that the presumption of innocence of the accused continues and therefore, he is to satisfy himself that the judgment of the trial Judge is correct. It is the bounden duty of the appellate Court, which may be the final Court of fact, to go through the evidence for himself, to assess it in proper perspective and to come to an independent finding. On careful examination of the impugned judgment, I have no hesitation to hold that the learned Sessions Judge has failed to discharge his duty as an appellate Court. As indicated above, he has simply summarized the submissions made before him by the leaned Public Prosecutor and has not cared to examine and scrutinize the evidence for himself. For the reasons aforesaid, the impugned judgment is vulnerable and, therefore, the appeal needs rehearing by him.

There appears to be force in the submission of the learned counsel for the petitioner with regard to the report submitted by the Deputy Government Examiner and Assistant Government Examiner of Questioned Documents. Section 293, Cr.P.C. dispenses with the proof of certain documents unless the court itself thinks it necessary to be proved. Sub-section (4) thereof provides that the said section applies to those Government Scientific experts mentioned therein. So far as handwriting expert is concerned, the Director of the Finger Print Bureau has been mentioned as the expert. It means that if the report is submitted by the Director of Finger Print Bureau,

33. *Sonam Tshering Bhutta v State of Sikkim*, 2004 Cr LJ 3136 (SC).
Also see: *Nirmal v State of Punjab*, 2002 Cr LJ 447 : 2001 (4) All Cr LR 219 : 2001 (4) Rec Cri R 623; *State of Maharashtra v Damu Gopinath Shinde*, AIR 2000 SC 1691 (1700) : 2000 AIR SCW 1617 : 2000 Cr LJ 2301.

the same may be admitted into evidence without he being formally examined. But in the present case, Exhibit 29 was not made by the Director of Finger Print Bureau. Therefore, it is necessary that handwriting expert who prepared Exhibit 29 should be examined to prove the contents thereof, in the interest of justice. The learned Sessions Judge is directed to summon the expert and examine him as a witness. For this, the prosecution will take necessary steps. After he is examined, the learned Sessions Judge will give adequate opportunity to the defence to cross-examine the witness. The evidence of the said witness will form part of the record and be available to be considered along with other evidence already on record.

From a perusal of the above it would be clear that section 293, Code of Criminal Procedure applies only to certain experts like Chemical examiner or Assistant Chemical Examiner to the Government. Chief Inspector of Explosives, Director of the Finger Print Bureau, Director, Deputy Director or Assistant Director of a Central Forensic Science laboratory or a State Forensic Science Laboratory and the Serologist to the Government, besides Director of Haffkeine Institute, Bombay.

The report of the handwriting expert, even if it has been given by the expert working in the Forensic Science laboratory, would not be per se admissible under section 293, Code of Criminal Procedure unless the maker of the said report is summoned and examined as a witness and the other side is given opportunity to cross examine the witness. In my opinion, there was absolutely no occasion for the learned Sessions Judge to have observed that the report of the handwriting expert was admissible under section 293, Code of Criminal Procedure and could be allowed to be tendered into evidence without summoning the author of the report.

In *State of Maharashtra v Damu Gopinath Shinde,* 2000 AIR SCW 1617 : 2000 Cr LJ 2301 : AIR 2000 SC 1691 (1700) opinion of the Assistant State Examiner of documents was produced in evidence as Ex. 64. Under these circumstances, it was held by their Lordships of the Supreme Court that from that description alone, it could not be gathered whether his office would fall within the purview of section 293 Code of Criminal Procedure and hence without examining the expert as a witness in the court, no reliance could be placed on Ex. 64.

In view of the above, in my opinion, even if the prosecution was allowed to produce the report of the handwriting expert by way of additional evidence, the learned Sessions Judge, had gone wrong in allowing the prosecution to tender the said report of the handwriting expert in evidence, without examining the expert and allowing opportunity to the accused to cross-examine him. As referred to above, this was contrary to law, inasmuch as such a report would not be covered under section 293, Code of Criminal Procedure.

For the reasons recorded above, while upholding the order of the learned Sessions Judge, allowing the prosecution to produce the report of the handwriting expert by way of additional evidence, the present petition is partly allowed and the order dated 23-9-2000, passed by the learned Sessions Judge, is modified and

it is directed that for proving the report of the handwriting expert, the prosecution would be given opportunity to examine the expert, who had given the said report and the accused would have the right to cross-examine the said witness.

37.21 TYPEWRITING IDENTIFICATION ADMISSIBLE[34]

Author's Summary

The SC in 1952 has ruled that the identification of typescript/typewriter is not a science and it is not covered under section 45 of the IEA. The present judgment has corrected the lacunae. It is a well-argued judgment supported by authorities. Typescript is now examined under the section 45 IEA. It should be applicable to computer prints also.

Highlights italicised

34. *State (through CBI/New Delhi) v S.J. Choudhary*, AIR 1996 SC 1491 : 1996 AIR SCW 1128 : 1996 Cr LJ 1713.

Relevant Extracts (Verbatim)

The reference made in this appeal to the constitution bench is for deciding the important question of law: Whether the opinion of a typewriter expert is admissible in evidence under section 45 of the Indian Evidence Act, 1872?

The respondent S.J. Chaudhary was being tried in the Court of Additional Sessions Judge, New Delhi, on charges punishable under section 302 of the Indian Penal Code and sections 3 and 4 of the Explosive Substances Act, 1908 in Sessions Case No. 36 of 1983. The prosecution wanted to examine a typewriter expert for proof of certain incriminating facts against the respondent based on the identity of a typewriter on which a material document was alleged to have been typed. An objection was taken to the admissibility of the opinion evidence of the typewriter expert under section 45 of the Indian Evidence Act, 1872 (for short "Evidence Act") based on the decision of this court in *Hanumant Govind Nargundkar v State of Madhya Pradesh*, AIR 1952 SC 343 : 1952 SCJ 509 : 1952 SCR 1091 and the trial court upheld that objection, Criminal Revision No. 105 of 1987 was filed in the Delhi High Court by the prosecution challenging that order. The Delhi High Court has dismissed the revision, hence this appeal by special leave.

The present criminal appeal came up for hearing before a Division Bench comprising of two learned Judges of this court. The correctness of the observations in *Hanumant Govind Nargundkar v State of Madhya Pradesh*, AIR 1952 SC 343 : 1952 SCJ 509 : 1952 SCR 1091 by a Bench of three learned judges on this point was doubted and reconsideration thereof was sought on behalf of the appellant. Accordingly, by order dated March 22, 1990 the Division Bench took the view that this important question of law involved in this appeal should be considered and decided by a larger Bench. This question of law is the only point involved for decision in this appeal and the decision thereon would dispose of the appeal.

In *Hanumant Govind* while dealing with one of the arguments advanced therein, it was stated thus:

> Next it was argued that the letter was not typed on the office typewriter that was in those days, *viz.,* article B, and that it had been typed on the typewriter article A which did not reach Nagpur till the end of 1946. On this point evidence of certain experts was led. The High Court rightly held that opinion of such experts was not admissible under the Indian Evidence Act as they did not fall within the ambit of section 45 of the Act. This view of the High Court was not contested before us. It is curious that the learned judge in the High Court, though he held that the evidence of the experts was inadmissible, proceeded nevertheless to discuss it and placed some reliance on it. The trial magistrate and the learned Sessions Judge used this evidence to arrive at the finding that, as the letter was typed on article A which had not reached Nagpur till the end of December, 1946, obviously the letter was antedated. Their conclusion based on inadmissible evidence has therefore to be ignored."

The above passage in that decision is the basis of the view taken that the opinion of a typewriter expert is not admissible under the Evidence Act and that it does not fall within the ambit of section 45 of the Act. It is significant that this view taken by the High Court in that case was not even contested in this court and, therefore, the decision in *Hanumant* proceeds on the concession that the evidence of a typewriter expert is not admissible in evidence under section 45 of the Act. In our opinion, the decision in *Hanumant* cannot be taken as deciding that point even though on the basis of that observation the evidence of typewriter expert was excluded as inadmissible. This question of law has, therefore, to be answered without any further assistance being available from the decision in *Hanumant*.

In the Indian Evidence Act, 1872, Chapter II relating to 'Relevancy of Facts' contains sections 5 to 55 and therein under the heading 'Opinions of Third Persons, when relevant' are sections 45 to 51. Section 45 reads thus:

> *Opinions of experts.*—When the court has to form an opinion upon a point of foreign law, or of science, or art, or as to identity of handwriting [or finger impressions] (Ins. by Act 5 of 1899, section 3), the opinions upon that point of persons specially skilled in such foreign law, science or art, [or in questions as to identity of handwriting] (Ins.

by Act 18 of 1872, section 4), [or finger impressions] (Ins. by Act 5 of 1899, section 3), are relevant facts.

Such persons are called experts.

Illustration (c) to section 45 is as under:

(c) The question is, whether a certain document was written by *A*. Another document is produced which is proved or admitted to have been written by *A*.

The opinions of experts on the question whether the two documents were written by the same person or by different persons are relevant.

The plain meaning of section 45 is that the court in order to form an opinion upon a point of foreign law, or of science, or art, or as to identity of handwriting, or finger impressions can treat the opinion upon that point of person specially skilled in such foreign law, science or art, or in questions as to identity of handwriting, or finger impressions as relevant facts. In other words, the opinion of persons specially skilled in such foreign law science, or art, or questions as to the identity of handwriting or finger impression, called experts therein, are relevant facts. The opinion of such experts is admissible in evidence as relevant facts by virtue of section 45 of the Evidence Act.

In our opinion, irrespective of the view taken on the question of meaning of the word handwriting in section 45 to include typewriting, the word 'science', occurring independently and in addition to the word 'handwriting' in section 45, is sufficient to indicate that the opinion of a person specially skilled in the use of typewriters and having the scientific knowledge of typewriters would be an expert in this science; and his opinion about the identity of typewriting for the purpose of identifying the particular typewriter on which the writing is typed is a relevant fact under section 45 of the Evidence Act. It is obvious that the Indian Evidence Act when enacted originally in 1872 did not specifically mention typewriting in addition to handwriting because typewriters were then practically unknown. However, the expression 'science', or in section 45 in addition to the expressions 'foreign law' and 'handwriting' use in the section as originally enacted, and the expression 'finger impressions' inserted in 1899 is sufficient to indicate that the expression 'science, or art' therein is of wide import. This expression 'science, or art' cannot therefore, have a narrow meaning in section 45 and each of the words 'science' and 'art' has to be construed widely to include within its ambit the opinion of an expert in each branch of these subjects, wherever the court has to form an opinion upon a point relating to any aspect of science or art.

The meaning of the word 'science' as understood ordinarily with reference to its dictionary meaning must be attributed to the word as used in section 45 of the Indian Evidence Act. Some of the meanings given in the dictionaries are:

The Oxford Encyclopaedic English Dictionary:

Science... a. systematic and formulated knowledge, esp. of a specified type or on a specified subject (political science), b. the pursuit or principles of this....

The New Shorter Oxford English Dictionary, Vol. 2.:

Science..... 2a. Knowledge acquired by study acquaintance with or mastery of a department of learning... 3a. A particular branch of knowledge or study; a recognised department of learning....

Collins Dictionary of the English Language:

Science 1. the systematic study of the nature and behaviour of the material and physical universe, based on observation, experiment, and measurement, and the formulation of laws to describe these facts in general terms. 2. the knowledge so obtained or the practice of obtaining it. 3. any particular branch of this knowledge: the pure and applied sciences. 4. any body of knowledge organised in a systematic manner. 5. skill or technique...

It is clear from the meaning of the word 'science' that the skill or technique of the study of the peculiar features of a typewriter and the comparison of the disputed typewriting with the admitted typewriting on a particular typewriter to determine whether the disputed typewriting was done on the same typewriter is based on a scientific study of

the two typewritings with reference to the peculiarities therein; and the opinion formed by an expert is based on recognised principles regulating the scientific study. The opinion so formed by a person having the requisite special skill in the subject is, therefore, the opinion of an expert in that branch of the science. Such an opinion is the opinion of an expert in a branch of science which is admissible in evidence under section 45 of the Indian Evidence Act.

There cannot be any doubt that the opinion of an expert in typewritings about the questioned typed document being typed on a particular typewriter is based on a scientific study of the typewriting with reference to the significant peculiar features of a particular typewriter and the ultimate opinion of the expert is based on scientific grounds. The opinion of a typewriter expert is an opinion of a person specially skilled in that branch of the science with reference to which the court has to form an opinion on the point involved for decision in the case. In our opinion, on a plain construction of section 45 giving to the word 'science' used therein its natural meaning, this conclusion is inevitable; and for supporting that conclusion, it is not necessary to rely on the further reason that the word 'handwriting in section 45 would also include typewriting.

Statutory Interpretation by Francis Bennion, Second edition, section 288 with the heading "Presumption that updating construction to be given" states one of the rules thus:

> *(2) It is presumed that Parliament intends the court to apply to an ongoing Act a construction that continuously updates its wording to allow for changes since the Act was initially framed (an updating construction). While it remains law, it is to be treated as always speaking. This means that in its application on any date, the language of the Act, though necessarily embedded in its own time, is nevertheless to be construed in accordance with the need to treat it as current law.*

In the comments that follow it is pointed out that an ongoing Act is taken to be always speaking. It is also, further, stated thus:

> *In construing an ongoing Act, the interpreter is to presume that Parliament intended the Act to be applied at any future time in such a way as to give effect to the true original intention. Accordingly the interpreter is to make allowances for any relevant changes that have occurred, since the Act's passing, in law, social conditions, technology, the meaning of words, and other matters. Just as the US Constitution is regarded as a living Constitution, so an ongoing British Act is regarded as 'a living Act'. That today's construction involves the supposition that Parliament was catering long ago for a state of affairs that did not then exist is no argument against that construction. Parliament, in the wording of an enactment, is expected to anticipate temporal developments. The drafter will try to foresee the future, and allow for it in the wording.*
>
> *An enactment of former days is thus to be read today, in the light of dynamic processing received over the years, with such modification of the current meaning of its language as will now give effect to the original legislative intention. The reality and effect of dynamic processing provides the gradual adjustment. It is constituted by judicial interpretation, year in and year out. It also comprises processing by executive officials.*

There cannot be any doubt that the Indian Evidence Act, 1872 is, by its very nature, an 'ongoing Act.'

It appears that it was only in 1874 that the first practical typewriter made its appearance and was marketed in that year by the E. Remington and Sons Company which later became the Remington typewriter. Obviously, in the Indian Evidence Act enacted in 1872 typewriting could not be specifically mentioned as a means of writing in section 45 of the Evidence Act. Ever since then, technology has made great strides and so also the technology of manufacturer of typewriters resulting in common use of typewriters as a prevalent mode of writing. This has given rise to development of the branch of science relating to the examination of questioned typewriting.

In 'Questioned Documents', Second Edition, by Albert S. Osborn in the Chapter of "questioned typewriting" this aspect is considered and, therein at page 598, it is stated thus:

The principles underlying the identification of typewriting are the same as those by which the identity of a person is determined or handwriting is identified. The identification in either case is based upon a definite combination of common or class qualities and features in connection with a second group of characteristics made up of divergences from class qualities which then became individual peculiarities.

The mathematical principles outlined in the fourteenth Chapter show how remote is the possibility of coincidence of even a few scars or deformities on a person, and coincidence of scars and deformities are as remote with typewriters as with persons.

In 'Photographic Evidence' by Charles C. Scott, Second Edition, Volume 1, under the heading "Typewriting Identity or Non-identity of Typing" it is stated thus:

But even as the nationality of an individual may be perplexing but does not in any way hamper the determination of his personal identity by means of his fingerprints, his handwriting, or other reliable indications, so also the fact that it is often difficult to determine the make of a typewriter used in typing a document does not lessen the reliability of the scientific determination that a certain typewritten document was typed on a particular machine regardless of its make. By the use of the proper microscopes and test plates the document examiner often can determine the question and by the use of photographic comparison charts he can demonstrate his findings, usually with unimpeachable certainty.

From a comparison of the typewriting on a document which is a subject of controversy with specimens known to have been made on a certain typewriter it is usually possible to determine whether or not what typewriter was used in typing the subject document, provided the subject document contains sufficient typewriting and the specimens from the known machine are of a suitable kind. This is true because every typewriter when it comes off the assembly line is an individual and writes exactly like no other typewriter. When a typewriter is brand new the differences between it and other typewriters coming off the assembly line at the same time are extremely minute and elusive, but theoretically at least there are identifying differences that can be discovered by microscopic examination and demonstrated photographically. Furthermore, the more a typewriter is used the more individualistic it becomes; and the easier it is to identify its typewriting. In some instances through overuse, misuse, or abuse a typewriter develops so many peculiarities that its typing can be identified readily with the naked eye.

In 'Law of Disputed and Forged Documents' by J. Newton Baker, while dealing with the basic principles of identification of typewriting generally it is stated:

...Since typewriting possesses individuality it can be compared and identified in the same manner as handwriting.....

Therein while discussing individuality of typewriting, it is stated thus:

The individuality of the typewriter is established by the character of its type impression on the paper. These characteristics of typewriting can be analysed, compared and differentiated and can be positively identified as those of a particular typewriter. This individual comparison and identification of characteristics may establish the genuineness or forgery of a typewritten instrument and when admitted in evidence is sufficient proof.

The occurrence of similar irregularities in typewriting in two or more machines is practically impossible. The rule that the typewriter creates for itself a certain distinctive character of writing which identifies one certain machine from all other machines is well-established. To prove that two instruments were written on a particular typewriter similar coincidences of characteristics must be shown in both instruments, and these coincidences considered collectively must demand a single conclusion.

In 'Typewriting Identification (Identification System for Questioned Typewriting)' by Billy Prior Bates, the conclusion of the principles is stated thus:

> *Conclusion.—TYPEWRITING identification is based on the same principle underlying handwriting identification, or any other thing which has a great number of possible variations.*
>
> *The identification of a typewritten document can be likened to the identification of a particular person. A person may be identified in general by his sex, size, features, etc., and in addition, for example, by a radical mastectomy scar. A typewriter may be identified in general by characteristics such as type, design and size, possessed by all machines of a specific make and model, and in addition, for example, by a flaw in the serif on the letter E.*
>
> *No opinion as to identity should be based upon only a few dissimilarities (or similarities). It is the combination of measurements and characteristics which all together make up the conclusion.*
>
> *When good, clear specimens are available in sufficient amount for a scientific identification of the twelve points of comparison, it is possible to show with absolute certainty that a document was, or was not, produced by a particular machine.*
>
> *The mathematical probability of the same combination of these characteristics divergent from the norm appearing in two machines is practically nil. The evidence of the twelve points of comparison can be conclusive proof.*

It is, therefore, clear that the examination of typewriting and identification of the typewriter on which the questioned document was typed is based on a scientific study of certain significant features of the typewriter peculiar to a particular typewriter and its individuality which can be studied by an expert having professional skill in the subject and, therefore, his opinion on that point relates to an aspect in the field of science which falls within the ambit of section 45 of the Indian Evidence Act. Such opinion evidence of experts in the field has long been treated as admissible evidence in similar jurisdictions like the United States as is evident from these standard text books on the subject.

In the present case, even without resort to the word 'handwriting' in section 45 to include typewriting therein, in the view we have taken, the word 'science' is wide enough to meet the requirement of treating the opinion of a typewriter expert as an opinion evidence coming within the ambit of section 45 of the Evidence Act. We may, however, add that the long accepted practice of judicial construction which enabled the reading of the word 'telegraph' to include 'telephone' within the meaning of that word in Acts of 1863 and 1869 when telephone was not invented, would also be available in the present case to read 'typewriting' within the meaning of word 'handwriting' in the Act of 1872. This is so because what was understood by handwriting in 1872 must now in the present times after more than a century of the enactment of that provision, be necessarily understood to include typewriting as well, since typing has become more common than handwriting and this change is on account of the availability of typewriters and their common use much after the statute was enacted in 1872. This is an additional reason for us to hold that the opinion of the typewriter expert in this context is admissible under section 45 of the Indian Evidence Act.

As a result of the above discussion, we hold that the observations made in the above extract in the decision in *Hanumant* on the basis of a concession does not reflect the correct position of law on this point and should, therefore, be treated as no longer good law on the point.

For the aforesaid reasons, we hold that the opinion of the typewriter expert in the present case is admissible under section 45 of the Evidence Act and the contrary view taken by the trial court and the High Court is erroneous. This appeal is accordingly allowed and the impugned orders of the trial court and the High Court are set aside.

37.22 PROOF OF POISONING[35]

Author's Summary

It is a case of murder by poisoning with extreme cunning and planning. The victim was a rich widow. She was being treated for diabetes by the family doctor. He was accompanying her to Mumbai one day. He gave her some poison or an over dose of insulin and she went into comma. He got her admitted in a Mumbai hospital where she died. The medico-legal expert could not find any cause of her death. However, they were sure that she did not die a natural death. The suspicion fell on the doctor. His whole past was investigated. Plenty of circumstantial evidence was found that he had been cheating her and probably he had killed her son also. Besides, his behaviour in handling her after coma was strong evidence of the murder.

All the three court were unanimous in the verdict that the family doctor had murdered the woman.

Highlights italicised

Our findings thus substantially accord on all the relevant facts with those of the two courts below, though the arrangement and consideration of the relevant evidence on record is somewhat different. It is now necessary to consider the arguments which have been advanced on behalf of the appellant. The first contention is that the essential ingredients required to be proved in all cases of murder by poisoning were not proved by the prosecution in this case. Reference in this connection is made to a decision of the Allahabad High Court in *Mt. Gajrani v Emperor*, AIR 1933 All 394 and to two unreported decisions of this court in *Chandrakant Nyalchand Seth v State of Bombay*, decided on February 19 1958.

In these cases, the court referred to three propositions which the prosecution must establish in a case of poisoning:

(a) that death took place by poisoning;

(b) that the accused had the poison in his possession; and

(c) that the accused had an opportunity to administer the poison to the deceased.

The case in Cr. A. No. 98 of 1958, D/-4-11-1958 (SC) turned upon these three propositions. There, the deceased had died as a result of poisoning by potassium cyanide, which poison was also found in the autopsy. The High Court had disbelieved the evidence which sought to establish that the accused had obtained potassium cyanide, but held, nevertheless, that the circumstantial evidence was sufficient to convict the accused in that case. The court did not, however, accept the circumstantial evidence as complete. It is to be observed that the three propositions were laid down not as the invariable criteria of proof by direct evidence in a case of murder by poisoning, because evidently if after poisoning the victim the accused destroyed all traces of the body, the first proposition would be incapable of being proved except by circumstantial evidence. Similarly, if the accused gave a victim something to eat and the victim died immediately on the ingestion of that food with symptoms of poisoning and poison, in fact, was found in the viscera, the requirement of proving that the accused was possessed of the poison would follow from the circumstance that the accused gave the victim something to eat and need not be separately proved, there have been cases in which conviction was maintained, even though the body of the victim had completely disappeared, and it was impossible to say, except on circumstantial evidence, whether that person was the victim of foul play, including poisoning. Recently, this court in *Mohan v State of Uttar Pradesh*,[3] decided on November 5, 1959, held that the proof of the fact of possession of the poison was rendered unnecessary, because the victim died soon after eating *pedas* given by the accused in that case, and he had not partaken any other food likely

35. *Anant Chintaman Lagu v State of Bombay*, AIR 1960 SC 500 : (1960) 2 SCR 460 : 1960 Cr LJ 682 (SC).

to contain poison. In *Dr. Palmer's* case, Notable Trials Series, strychnine was not detected, and the accused was convicted by the jury after Lord Chief Justice Campbell (Cresswell, J. and Mr. Baron Alderson concurring) charged the jury that the discovery of the poison on autopsy, was not obligatory, if they were satisfied on the evidence of symptoms that death had been caused by the administration of strychnine. The conduct of Palmer, which was also significant, was stressed inasmuch as he had attempted to thwart a successful chemical analysis of the viscera and had done suspicious acts to achieve that end. In *Dr. Crippen's* case,[1] the conduct of the accused after the death of Mrs. Crippen in making the friends and relatives believe that Mrs. Crippen was alive, was considered an incriminatory circumstance pointing to his guilt. No doubt, in *Dr. Crippen's* case, the body was found and poison was detected, but there was no proof that *Dr. Crippen* had administered the poison to her, that being inferred from his subsequent conduct in running away with Miss Le Neve. In the second case of this court, the poison was available to the victim, and it was possible that she had taken it to end an unhappy life.

The cases of this court which were decided, proceeded upon their own facts, kept in mind always, the sufficiency of the evidence, direct or circumstantial.

To establish murder by poisoning will depend on the facts of each case. If the evidence in a particular case does not justify the inference that death is the result of poisoning because of the failure of the prosecution to prove the fact satisfactorily, either directly or by circumstantial evidence, then the benefit of the doubt will have to be given to the accused person. But if circumstantial evidence, in the absence of direct-proof of the three elements, is so decisive that the court can unhesitatingly hold that the death was a result of administration of poison (though not detected) and that the poison must have been administered by the accused person, then the conviction can be rested on it.

* * * * *

In (1952) NZLR 111, where the entire case law in England was presented for the consideration of the court, it was pointed out by the court that there was no rule in England that *corpus delicti* must be proved by d irect evidence establishing the death of the person and further, the cause of that death. Reference was made to *Evans v Evans*,[2] where it was ruled that *corpus delicti* might be proved by direct evidence or by "irresistible grounds of presumption". In the same case, it has been pointed out that in New Zealand the court upheld numerous convictions, where the body of the victim was never found.

The rule of law stated by Sir Matthew Hale in Pleas of the Crown Vol. 2, p. 290, that "I would never convict any person of murder or manslaughter, unless the fact were proved to be done, or at least the body found dead" was not accepted in this and other cases. Lord Goddard also rejected the statement as one of universal application, in the case to which we have already referred.

The case of *Mary Ann Nosh*,[1] is illustrative of the proposition that even though the cause of death may not appear to be established by direct evidence the circumstances of the case may be sufficient to infer that a murder has been committed. In that case, the prisoner had an illegitimate son, 5 years old. There was evidence to show that the mother desired to put the child out of her way. One day in June, 1907, the mother left the house and returned without the child. She made several statements as to what had happened to the child, which were found to be untrue. As late as April 1908, the body of a child was discovered in a well. Decomposition had so far advanced that even the sex of the child could not be determined. There was nothing, therefore, to show whether death was natural or violent, or whether it had occurred before or after the body was put into the well. The case was left to the jury. On appeal, it was contended that there being no proof of how death took place, the judge should not have left the case to the jury but ought to have withdrawn it. Lord Chief Justice delivering the judgment of the Court of Appeal referred to the untrue statements of the prisoner about the whereabouts of the child, and observed as follows:

All these statements were untrue. She had an object in getting rid of the child, and if it had been lost or met with an accidental death, she had every interest in saying so at once. It is said there is no evidence of violent death, but we cannot accept that Mr. Goddard cannot

have meant that there must be proof from the body itself of a violent death....In view of the facts that the child left home well and was afterwards found dead, that the appellant was last seen with it, and made untrue statements about it, this is not a case which could have been withdrawn from the jury.

* * * * *

A case of murder by administration of poison is almost always one of secrecy. The poisoner seldom takes another into his confidence, and his preparations for the commission of the offence are also secret. He watches his opportunity and administers the poison in a manner calculated to avoid its detection. The greater his knowledge of poisons, the greater the secrecy, and consequently the greater the difficulty of proving the case against him. What assistance a man of science can give he gives; but it is too much to say that the guilt of the accused must, in all cases, be demonstrated by the isolation of the poison, though in a case where there is nothing else such a course would be incumbent upon the prosecution. There are various factors which militate against successful isolation of the poison and its recognition. The discovery of the poison can only take place either through a post-mortem examination of the internal organs or by chemical analysis. Often enough, the diagnosis of poison is aided by the information which may be furnished by relatives and friends as to the symptoms found on the victim, if the course of poison has taken long and others had an opportunity of watching its effect. Where, however, the poison is administered in secrecy and the victim is rendered unconscious effectively, there is nothing to show how the deterioration in the condition of the victim took place and if no poison but the disease is suspected, the diagnosis of poisoning may be rendered difficult. In *Champman's* case. Notable Trials Series, the victim (Maudmarsh) was sent to Guys Hospital, where the doctors diagnosed her condition to be due to the various maladies "including cancer, rheumatism and acute dyspepsia." It is clear that doctors can be deceived by the symptoms of poison into believing that they have a genuine case of sickness on hand. In *Dr. Palmer's* case, Notable Trials Series, two medical witnesses for the defence diagnosed the case from the symptoms as being due to Angina Pectoris or epilepsy with the tetanic complications.

The reason for all this is obvious. Lambert in his book, "*The Medico-Legal Post-mortem in India*" (pp. 96, 99-100) has stated that the pathologist's part in the diagnosis of poisoning is secondary and has further observed that several poisons, particularly of the synthetic hypnotics and vegetable alkaloids groups, do not leave any characteristic signs which can be noticed on post-mortem examination, (see Modi's "*Medical Jurisprudence and Toxicology*", 13th Edition, pages 450-451 and Taylor's "*Principles and Practice of Medical Jurisprudence*", Volume II, page 229). The same is stated by Otto Saphir in his book "*Autopsy*" at pp. 71 and 72. In Dreisbach's "*Handbook of Poisons*" 1955, it is stated that pathological findings in deaths from narcotic analgesics are not characteristic. He goes further and says that even the laboratory findings are non-contributory. The position of the pathologist who conducts a post-mortem examination has been summed up by Modi in "*Medical Jurisprudence and Toxicology*", 13th Edn., p. 447 as follows:

In order to make a probable guess of the poison and to look for its characteristic post-mortem appearances, it is advisable that a medical officer, before commencing a post-mortem examination on the body of a suspected case of poisoning, should read the police report and endeavour to get as much information as possible from the relatives of the deceased regarding the quality and quantity of the poison administered, the character of the symptoms with reference to their onset and the poison and the development of the first symptoms, the duration of the illness, nature of the treatment adopted, and the time of death. He will find that in most cases the account supplied by the police and the relatives is very meagre, or incorrect and misleading. His task is, therefore, very difficult, especially when many of the poisons except corrosives and irritants do not show any characteristic post-mortem signs and when bodies are in an advanced state of decomposition.....

Similarly, Gonzales' *Legal Medicine and Toxicology*' states at p. 629:

The question of whether or not a negative toxicological examination is consistent with death by poison can be answered affirmatively, as many persons overcome by carbon monoxide

die after twenty-four hours, at which time the gas cannot be determined in the blood by chemical tests. Likewise, the organs of individuals who have been poisoned by phosphorus may not contain the toxic substance responsible for the death if they have managed to survive its effects for several days.

Many conditions seriously interfere with the toxicological examination, such as post-mortem decomposition.....

We need not multiply authorities, because every book on toxicology begins with a statement of such a fact. Of course, there is a chemical test for almost every poison, but it is impossible to expect a search for every poison. Even in chemical analysis, the chemical analyser may be unsuccessful for various reasons. Taylor in his "*Principles and Practice of Medical Jurisprudence*" (Vol. II, p. 228), gives three possible explanations for negative findings, *viz*., (1) the case may have been of disease only; (2) the poison may have been eliminated by vomiting or other means or neutralized or metabolized; and (3) the analysis may have been faultily performed.

Svensson and Wendel in "*Crime Detection*" have stated at p. 281 that:

Hypnotics are decomposed and disappear very quickly some even in the time which elapses between the administration and the occurrence of death.

Circumstantial evidence in this context means a combination of facts creating a network through which there is no escape for the accused, because the facts taken as a whole do not admit of any inference but his guilt. To rely upon the findings of the medical man who conducted the post-mortem and of the chemical analyser as decisive of the matter is to render the other evidence entirely fruitless. While the circumstances often speak with unerring certainty the autopsy and the chemical analysis taken by themselves may be most misleading. No doubt, due weight must be given to the negative findings at such examinations. But, bearing in mind the difficult task which the man of medicine performs and the limitations under which he works, his failure should not be taken as the end of the case, for on good and probative circumstances, an irresistible inference of guilt can be drawn.

In the present case, the effort of the appellant has been to persuade the court that the death of Laxmibai was possibly the result of disease rather than by poison. During the course of the case and the appeal, various theories have been advanced and conflicting diagnoses have been mooted. The case of the appellant has wavered between death by diabetic coma and by hypoglycemia, though relying upon the condition of the arteries and the aorta and the rigidity of the neck, suggestions of coronary complications and renal failure have also been made. We have shown above that this was not a case of diabetic coma because of the absence of the cardinal symptoms of diabetic coma. This also is the opinion of Dr. Variava and Dr. Mehta, though Dr. Jhala, for reasons which we have indicated, accepted it.

The appellant argued again the case from the angle of diabetic coma, but later veered in favour of hypoglycemia. This change is noticeable not only in the arguments before us but also throughout the conduct of the case is merely to confuse the issue, and create, if possible a doubt, which would take the mind away from the surrounding circumstances and focus it only upon the medical aspect of the case. Full advantage has been taken of the findings of Dr. Ugale and Dr. Miss Aneeja, which suggest partly an onset of diabetic coma, partly of hypoglycemia and partly of renal failure. There is no true picture of any one disease. The rigidity of the neck was not reflected in the chemical analysis of the cerebro-spinal fluid and was negatived, in so far as renal failure is concerned, by the negative findings about albumen. Diabetic coma stood ruled out by the presence of the Babinsky sign and the suddenness of the onset, the negative aspect of acetone and the rather remarkable failure of the specific treatment given for it to have worked any change. Driven from these considerations to such doubtful suggestions as coronary complications of which no physical evidence was found by Dr. Jhala, the appellant put his case on hypoglycemia, and relied upon the fact that at the hospital 40 units of insulin intravenously and another 40 units subcutaneously were administered. Medical text-books were quoted to show that in the case of the hypoglycemic coma the introduction of even a small quantity of insulin sometimes proves fatal. The learned advocate general stoutly resisted this move, which was at variance with the

case as set out before the High Court, because it is obvious enough that if one accepted the theory of hypoglycemic coma, the only injections of insulin causing such shock would be proved to have been given at the hospital and not by the appellant. Here, the position, however, is not so difficult for the state, because Laxmibai was found to have 4 oz. of pasty meal in her stomach, and with food inside her, the possibility of hypoglycemia taking place naturally was extremely remote. If it was hypoglycemic coma due to excessive administration of insulin, then it must have been administered prior to its onset, and who could have given it but the appellant? Even though coma supervenes suddenly, the patient passes through symptoms of discomfort, and Laxmibai would have told the appellant about it in the train. The appellant mentioned nothing of this to Dr. Ugale. If an excessive dose of insulin was given by the appellant, the question of intent would arise, and the conduct shows the intention. There were no pronounced symptoms of hypoglycemia either. Laxmibai just passed from unconsciousness to death without the manifestation of any of the signs associated with the syndrome of hypoglycemic death. It is also to be remembered that hypoglycemic coma is generally overcome by the administration of a very small quantity of glucose 5 or 10 grams of glucose orally: Treatment of Diabetes Mellitus by Joslin, Root and White, p. 350). The 40 units given intravenously were mixed with 20 c.c. of glucose and carried the palliative with them. Even otherwise, Laxmibai was receiving glucose by intragastric drip, and during the three and a half hours there should have been an improvement. The surprising part is that the administration of the insulin and glucose brought about no visible symptoms in the patient either for better or for worse. She passed into death, and the inference can only be that she did not die of these diseases of which she was either suspected or for which she was treated but of something else, which could not answer to the treatment given to her.

Dreisbach in his Handbook on Poisons at page 27 has stated that coma also results from the action of several poisons. Depressants, sedatives and hypnotics all cause death by coma (ibid, p. 201). The symptoms, according to the author, are sleepiness, mental confusion, unsteadiness rapidly followed by coma with slow, shallow respiration, flaccid muscles and absent deep reflexes. The difference between coma due to disease and coma as the result of poisons is stated by him in the following words:

> *Coma from poisoning presumably results from some interference with brain cell metabolism. In attempting to combat the effects of drugs which induce coma, remember that no agents are known which will specifically overcome the metabolic derangements of drug-induced coma. The mechanism of action of cerebral stimulant drugs is also unknown, but these drugs presumably act by depressing some inhibiting function in the cell. There is no evidence that any stimulants specifically oppose the cellular metabolic depression induced by depressant drugs such as the barbiturates.*

No specific antidote is known for the sedative and hypnotic drugs (ibid., p. 202).

The condition of Laxmibai clearly indicated an impairment of the central nervous system. It is no doubt true that in some cases of coronary thrombosis, coma supervenes; but it is idle to suggest in the present case that Laxmibai was afflicted by this type of coma, because Dr. Jhala who performed the post-mortem examination and opened the coronary arteries found no evidence of thrombosis. According to Otto Saphir, a myocardial infarct is easily detected (Autopsy, p. 301-302). Coma in Laxmibai's case, as we have shown above, was not the result of acidosis, hypoglycemia, renal failure or meningeal irritation. Her liver, pancreas and kidneys were found to have no pathological lesions and it is significant that no question was even attempted to establish that the opinion of Dr. Jhala on this part of the case was incorrect. Learned counsel for the appellant suggested that the examination by Dr. Jhala might have been superficial, and might not have included a microscopical examination of sections of some of the vital organs normally affected by diabetes. This suggestion, in our opinion ought to have been put forward during the cross-examination of the witness, and it is unfair now to suggest that the opinion that no lesions were found was based on either improper or inadequate examination. We hold that Dr. Jhala performed the examination adequately, and he was also helped by his assistants.

Here, we pause to ask a question of why the appellant brought up the question of hysterical fits at all. He could have said that Laxmibai was a diabetic, and that it was likely she had coma by reasons of that disease. The suggested diagnosis given by the appellant was so unlikely that Dr. Ugale questioned it then and there. There is nothing in the Wanlesswadi T.B. Sanatorium

papers or in Dr. Sathe's evidence to show that Laxmibai had hysterical fit after her hysterectomy operation. No suggestion was made to the doctors in court that Laxmibai might have had hysterical fits. The condition of the muscles and the absence of deep reflexes clearly show that this was just another piece the appellant gave the full particulars to Dr. Miss Aneeja. No suggestion was made to her or to Dr. Ugale that any information other than what was noted in the case papers was furnished. There is no case for holding that Laxmibai had a relapse of hysterical fits.

It would, therefore, appear that Laxmibai's condition was not due to any disease, because diseases inducing coma generally leave some trace behind, and also respond to medication. No doubt, in some cases the pathological findings after death from diabetic coma have been negative, but the question is, if this was such a case. We have, on the one hand, the fact that numerous poisons causing coma leave no identifiable trace in the victim after death, and, on the other, that sometimes the autopsy does not disclose any discoverable signs in a patient who dies after an attack of diabetic coma or disease. The appellant can be presumed to have had knowledge of these poisons. The appellant challenged the Advocate General to show from any standard book that the symptoms found by the doctors accorded with any known poison. Here, it must also be remembered that a man with knowledge may manipulate not one but more drugs to achieve his purpose, and the cardinal signs of poisoning on the victim may, as a result, be either obliterated or, at least significantly modified.

We give one example on which a certain amount of knowledge is possessed even by laymen. A poison of which one of the symptoms would be the contracting of the pupils of the eyes may be side-tracked by putting into the eyes of the victim a drug like atropine, which by its local action dilates the pupils. We give this example, because most of us know the action of atropine on the eyes, and because the knowledge may confuse the symptoms by a simple trick. We are not suggesting that this is what has happened in this case; but when we have to deal with a case of crime versus natural death, we cannot overlook the possibility of some ingenious artifice having been used to screen the action.

If Laxmibai died in circumstances which prima facie admit of either disease or homicide by poisoning, we must look at the conduct of the appellant who brought her to the hospital, and consider to what conclusion that conduct unerringly points. If the appellant as an honest medical man had taken Laxmibai to the hospital and she had died by reason of disease, his conduct would have been entirely different. He would not have taken her to the hospital bereft of property with which she started from home; he would not have given a wrong history of her ailments; he would not have written a letter suggesting that she had a brother in Calcutta, which brother did not exist, he would not have abandoned the corpse to be dealt with by the hospital as an unclaimed body, he would not have attempted to convince the world that she was alive and happily married; he would not have obtained her property by forgeries, impersonation and other tricks indulged in both before and after her death; but he would have informed her relatives and done everything in his power to see that she was properly treated and stayed on to face whatever inquiry the hospital wished to make into the cause of death and not tried to avoid the post-mortem examination and would not have disappeared, never to reappear. His prevarications about where Laxmibai was, make a big and much varied list, and his forgeries cover scores of documents. In the words of Baron Parke in Towell's case.[1]

> *Circumstantial evidence is the only evidence which can in cases of this kind, lead to discovery. There is no way of investigating them except by the use of circumstantial evidence: but it most frequently happens that great crimes committed in secret leave behind them some traces, or are accompanied by some circumstances which lead to the discovery and punishment of the offender.....Direct evidence of persons who saw the fact if that proof is offered upon the testimony of men whose veracity you have no reason to doubt is the best proof: but, on the other hand, it is equally true with regard to circumstantial evidence that the circumstances may often be so clearly proved, so closely connected with it, or leading to one result in conclusion. That the mind may be as well convinced as if it were proved by eye-witnesses.*

The appellant, in this case, took some risk in taking Laxmibai to the hospital and in giving his name there; and these aspects were, in fact, stressed as arguments in the case. As regards the first part, the argument overlooks that what appears to us to be a risk might not have so appeared to the appellant, who might have been sure of his own ability to screen himself. To him, the death of Laxmibai at the hospital without the discovery of poison would be the greatest argument in his favour that he had acted honestly. The second argument is equally unacceptable to us. The appellant could not take the risk of a false name and address if he was intending that the body should be disposed of as unclaimed. By giving his own address he could keep the strings in his own hands. If he gave an address and no reply came from that address, the hospital would suspect foul play. If he gave the address of Laxmibai, people in Poona would know of this mysterious death, and they would remember the death of Purshottam *alias* Arvind in 1954. At that time a post-mortem examination on the body of Arvind was held (*see*, evidence of Ramachandra (P.W. 1), and the explanation of the appellant given in writing on January 22, 1954, is set out below in his own words:

> *My name is Anant Chintaman Lagu, age.....years, residing at No. 431/5, Madiwale Colony, Poona, on being questioned by the state that I am the family doctor of Karve family in H. No. 94/95, Shukrawar. The deceased Purshottam Anant Karve belongs to that family. He came from Bombay to Poona on Saturday, the 16th January, 1954. He had come to me on Sunday the 17th January, 1954, for medicine for weakness. I treated him for 2 days, on 17th and 18th. He had neither told me that there was poisoning in his stomach, nor did I detect any even when I examined and treated him. He became unconscious 5 hours before his death. He was taken to the Sassoon Hospital at 9 P.M. on 18th January, 1954. He was taken to the Sasoon hospital because his disease increased in unconsciousness and also because his mother as also myself and Dr. Joshi were of the same opinion. He died there in about 30 to 45 minutes. The fact that there was deliberate poisoning by somebody, was neither revealed in my examination nor did Purshottam Karve speak to me anything about it during the time I treated him 2 days before. What exactly was the cause of death could not be revealed during my treatment. I do not know if somebody is on bad terms with him. There are rumours about suicide but there is no reason or any circumstance whatsoever for doing so.*

A false address would have started enquiries at the hospital end. Laxmibai's own address would have started speculation in Poona. It was for this reason that the appellant had to choose another place and to trim between fact and fiction so that he might be able to deal with the matter himself. Of course, Laxmibai did have an address of her own which could have been given, and which did not cease to be her address because she had got an attack of coma, from which people are known to recover.

These arguments, however, are of no avail, in view of the appellant's entire conduct now laid bare, which conduct has been proved to our satisfaction to have begun not after the death of Laxmibai but much earlier. This conduct is so knit together to make a network of circumstances pointing only to his guilt. The case is one of extreme cunning and premeditation. The appellant, whose duty it was to care for this unfortunate lady as a friend and as her medical adviser, deliberately set about first to ingratiate himself in her good opinion, and becoming her confidante found out all about her affairs. All this time he was planning to get at her property after taking her life. He did not perpetrate his scheme at Poona, where the death might have brought a host of persons to the hospital. He devised a diabolical scheme of unparalleled cunning and committed an almost perfect murder. But murder though it hath no tongue, speaks out sometimes. His method was his own undoing; because even the long arm of coincidence cannot explain the multitude of circumstances against him, and they destroy the presumption of innocence with which law clothes him. In our judgment, the two courts below were perfectly correct in their conclusion that the death of Laxmibai was the result of the administration of some unrecognized poison or drug which would act as a poison, and that the appellant was the person who administered it. We accordingly confirm the conviction.

37.23 CONTRABAND QUANTITY IN MIXTURES[36]

Author's Summary

It is a landmark judgment on Narcotics. The Amendment of the NDPS Act has drastically changed the punishment pattern. Now it is based on the quantity of the drug recovered. Law specified 3 categories small quantity (5 g), commercial quantity, (250 g) and the intermediate quantities (5-250 g).

The Narcotics are handled in mixtures. There was confusion whether the weight of the mixture or of the drug in the mixture should be considered for punishment. The SC decided in favour of the latter.

Highlights italicised

Relevant Extracts (Verbatim)

The relevant facts of the case are that on 5-3-2001, the Intelligence Officer was informed by an informant that two persons with certain drugs would be arriving by a Tamil Nadu Transport Corporation Bus at Thiruvananthapuram Bus Stand. The Officer along with other persons and the informant went to the bus stand and waited for the bus. At about 9.00 a.m., the two accused alighted from the Tamil Nadu Transport Corporation bus. They were identified by the informant. They were intercepted by the officials. The officials disclosed their identity and the accused were searched. When asked about possession of narcotic drugs, it was admitted by the accused that they were carrying 4 kg. of heroin and they handed over the bag to the Officer. The bag contained two packets wrapped in Tamil newspapers secured with brown adhesive tape in which light grey powder was found. Two samples of 5 gms. each from both the drug packets were packed, sealed and sent for testing to the Laboratory. The accused were arrested, but the second accused escaped while on the way to produce them before the Magistrate. On 26-3-2001, the Customs House Laboratory, Cochin sent a report confirming the samples as answering to the test of crude heroin, a narcotic drug covered under the N.D.P.S. Act. The report further said that the Laboratory was not equipped to conduct a quantitative test. Thus, the samples were sent for quantitative test. On 22-2-2002, a quantitative test was done in the Customs Laboratory, Chennai where the purity was tested and the quantitative test report indicated as follows:

S. No.	Marking on the cover	Lab No.	Wt. of the sample received with plastic cover	Wt. of the remnant received with plastic cover
1.	S1	235	5.6 g	5.0 g Purity 1.4%
2.	S2	236	4.9 g	4.6 g Purity 1.6%

3. The accused-appellant was charged with the offence committed under section 8(c) read with sections 21 and 29 of the N.D.P.S. Act by the Intelligence Officer, Narcotic Control Bureau. The Special Judge for Trial of Cases under the N.D.P.S. Act found that the substance found in possession of the accused was an opium derivative which has been defined under section 2(xvi), and under section 2(xvi)(e) a preparation, containing more than 0.2% of morphine or diacetylmorphine, is an opium derivative; and that since this contraband article contained 1.4% and 1.6% heroin it is an opium derivative, and punishable under section 21 of the N.D.P.S. Act. Since the manufactured drug being carried weighed 4.07 kg., it would come under section 21(c) being a commercial quantity, but since the accused is only a carrier and is not the beneficiary of the transaction, he would not be awarded the maximum sentence and would be awarded the minimum sentence of

36. *E. Micheal Raj v Intelligence Officer, Narcotic Control Bureau*, AIR 2008 SC 1720 : 2008 Cr LJ 2250.

10 years' rigorous imprisonment and a fine of rupees one lakh, in default of payment of fine rigorous imprisonment for one more year. On an appeal being preferred, the High Court found the accused guilty. The High Court said that section 21 of the N.D.P.S. Act when read with section 2(xi) which defines manufactured drug, makes it evident that the packet seized from the appellant is a manufactured drug. The offence can be in respect of the manufactured drug as well as preparation of manufacture drug. Preparation has been defined in section 2(xx). Again, any mixture of narcotic drug with other substances will also come within section 21 of the N.D.P.S. Act, so the rate of purity becomes irrelevant. The purity test does not advance the case of the accused. As per the High Court, it is the whole quantity of mixture which has to be taken into consideration for imposing the punishment under section 21 of the N.D.P.S. Act. The High Court maintained the conviction and sentence awarded by the Special Judge.

4. The only submission made by Shri K.V. Viswanathan, learned counsel for the appellant is confined to the limited issue relating to the sentence of the appellant under section 21 of the N.D.P.S. Act. As per the learned counsel, the conviction and sentence of the appellant are contrary to law because the total quantity of contraband seized from him was 4.07 kg. Since the purity of heroin is 1.4% and 1.6% respectively in two samples, therefore the quantity of heroin in possession is only 60 g. [(1.4+1.6)/2 = 1.5% of 4.07 kg. = 60 gs.). Thus, the total quantity of heroin seized is below 250 g., *i.e.,* below the commercial quantity. It is submitted that it is not the total weight of the substance allegedly recovered that is material, but the percentage content of heroin translated into weight that is relevant.

5. On the other hand, Shri Vikas Sharma, learned counsel appearing for the respondent urged that it is only the weight of the substance found in possession of the appellant and recovered from him ought to be seen, and once the substance tested positive for heroin, its percentage content in the substance was irrelevant, the entire substance would be viewed as a narcotic drug and consequently the total weight of the substance ought to be taken into consideration for determining whether it was a small quantity or a commercial quantity.

6. The provisions of the N.D.P.S. Act were amended by the Narcotic Drugs and Psychotropic Substances (Amendment) Act, 2001 (Act 9 of 2001) (w.e.f 2-10-2001), which rationalised the punishment structure under the N.D.P.S. Act by providing graded sentences linked to the quantity of narcotic drugs or psychotropic substances carried. Thus, by the Amending Act, the sentence structure changed drastically. Small quantity and commercial quantity were defined under section 2(xxiiia) and section 2(viia) respectively. New section 21 also provides for proportionate sentence for possessing small, intermediate and commercial quantities of offending material. As per Entry 56 of the Notification dated 19-10-2001 issued by the Central Government which deals with heroin, small quantity has been mentioned as 5 g. and commercial quantity has been mentioned as 250 g. So, the basic question for decision is whether the contravention involved in this case is small, intermediate or commercial quantity under section 21 of the N.D.P.S. Act, and whether the total weight of the substance is relevant or percentage of heroin content translated into weight is relevant for ascertaining the quantity recovered from the accused.

7. To appreciate the arguments of the parties, the relevant sections of the N.D.P.S. Act have to be looked into, which are as under: section 2(viia) (inserted by Amending Act 9 of 2001 w.e.f. 2-10-2001).

'Commercial quantity', in relation to narcotic drugs and psychotropic substances, means any quantity greater than the quantity specified by the Central Government by notification in the Official Gazette; section 2(xxiiia) (inserted by Amending Act 9 of 2001 w.e.f. 2-10-2001).

'Small quantity', in relation to narcotic drugs and psychotropic substances, means any quantity lesser than the quantity specified by the Central Government by notification in the Official Gazette; section **2(xvi).**

'Opium derivative' means—

(a) **Medicinal opium,** that is, opium which has undergone the processes necessary to adapt it for medicinal use in accordance with the requirements of the Indian Pharmacopoeia or any other Pharmacopoeia notified in this behalf by the Central Government, whether in powder form or granulated or otherwise or mixed with neutral materials;

(b) **Prepared opium,** that is, any product of opium by any series of operations designed to transform opium into an extract suitable for smoking and the dross or other residue remaining after opium is smoked;

(c) **Phenanthrene alkaloids,** namely, morphine, codeine, thebaine and their salts;

(d) **Diacetylmorphine,** that is, the alkaloid also known as diamorphine or heroin and its salts; and

(e) **All preparations** containing more than 0.2 per cent of morphine or containing any diacetylmorphine;

Section 2 (xi)

'Manufactured drug means—(a) All coca derivatives, medicinal cannabis, opium derivatives and poppy straw concentrate;

(b) Any other narcotic substance or preparation which the Central Government may, having regard to the available information as to its nature or to a decision, if any, under any International Convention, by notification in the Official Gazette, declare to be a manufactured drug; but does not include any narcotic substance or preparation which the Central Government may, having regard to the available information as to its nature or to a decision, if any, under any International Convention, by notification in the Official Gazette, declare not to be a manufactured drugs.

Section 21. *Punishment for contravention in relation to manufactured drugs and preparations [substituted by the Amending Act 9 of 2001, w.e.f. 2-10-2001]: Whoever, in contravention of any provision of this Act or any rule or order made or condition of licence granted thereunder, manufactures, possesses, sells, purchases, transports, imports inter-State, exports inter-State or uses any manufactured drug or any preparation containing any manufactured drug shall be punishable,—*

(a) where the contravention involves small quantity, with rigorous imprisonment for a term which may extend to six months, or with fine which may extend to ten thousand rupees, or with both;

(b) where the contravention involves quantity, lesser than commercial quantity but greater than small quantity, with rigorous imprisonment for a term which may extend to ten years, and with fine which may extend to one lakh rupees;

(c) where the contravention involves commercial quantity, with rigorous imprisonment for a term which shall not be less than ten years but which may extend to twenty years and shall also be liable to fine which shall not be less than one lakh rupees but which may extend to two lakh rupees:

Provided that the court may, for reasons to be recorded in the judgment, impose a fine exceeding two lakh rupees.

8. The Statement of Objects and Reasons concerning the Amending Act of 2001 is as follows:

> Narcotic Drugs and Psychotropic Substances Act, 1985 provides deterrent punishment for various offences relating to illicit trafficking in narcotic drugs and psychotropic substances. Most of the offences invite uniform punishment of minimum of ten years' rigorous imprisonment which may extend up to twenty years. While the Act envisages severe punishments for drug traffickers, it envisages reformative approach towards addicts. In view of the general delay in trial it has been found that the addicts prefer not to invoke the provisions of the Act. The strict bail provisions under the Act add to their misery.

Therefore, it is proposed to rationalise the sentence structure so as to ensure that while drug traffickers who traffic in significant quantities of drugs are punished with deterrent sentences, the addicts and those who commit less serious offences are sentenced to less severe punishment. This requires rationalisation of the sentence structure provided under the Act. It is also proposed to restrict the application of strict bail provisions to those offenders who indulge in serious offences.

9. The entry of the Notification under which the substance found in possession of the appellant falls is Entry 56 or Entry 239. The relevant portion of the Notification dated 19-10-2001 issued by the Central Government reads as under:

> S.O. 1055(E), dated 19-10-2001. In exercise of the powers conferred by clauses (viia) and (xxiiia) of section 2 of the Narcotic Drugs and Psychotropic Substances Act, 1985 (61 of 1985) and in supersession of Ministry of Finance, Department of Revenue Notification S.O. 527(E), dated 16th July, 1996, except as respects things done or omitted to be done before such supersession, the Central Government hereby specifies the quantity mentioned in columns 5 and 6 of the Table below, in relation to the narcotic drug and psychotropic substance mentioned in the corresponding entry in columns 2 to 4 of the said Table, as the small quantity and commercial quantity respectively for the purposes of the said clauses of that section.

Sl. No	Name of Narcotic Drug[37]	Small Quantity (in gm)	Commercial Quantity (in g./kg.)
56	Heroin Diacetylmorphine	5	250 g

Any mixture or preparation that of with or without a neutral material, of any of the above drugs.

* Lesser of the small quantity between the quantities given against the respective narcotic drugs or psychotropic substances mentioned above forming part of the mixture.

** Lesser of the commercial quantity between the quantities given against the respective narcotic drugs or psychotropic substances mentioned above forming part of the mixture.

10. The possession of offending substance would be considered an offence punishable under the N.D.P.S. Act, as heroin is an opium derivative as per section 2(xvi)(e) which says that all preparations containing more than 0.2 per cent of morphine or containing any diacetylmorphine is an opium derivative. Further, according to section 2(xi), all opium derivatives fall under the category of manufactured drug.

Thus, we conclude that the offending substance is an opium derivative and hence a manufactured drug, the possession of which is in contravention of the provisions of section 8 of the N.D.P.S. Act which prohibits certain operations to the effect that no person shall produce, manufacture, possess, sell, purchase, transport, warehouse, use, consume, import inter-State, export inter-State, import into India, export from India or tranship any narcotic drug or psychotropic substance.

11. *In the present case, the opium derivative which has been found in possession of the accused-appellant is prohibited under section 8 of the N.D.P.S. Act and thus punishable under section 21 thereof. The question is only with regard to the quantum of punishment.*

12. As a consequence of the Amending Act, the sentence structure underwent a drastic change. The Amending Act for the first time introduced the concept of commercial quantity in relation to narcotic drugs or psychotropic substances by adding clause (viia) in section 2, which defines this term as any quantity greater than a quantity specified by the Central Government by notification in the Official Gazette. Further, the term 'small quantity' is defined in section *2,* clause (xxiiia), as any quantity lesser than the quantity specified by the Central Government by notification in the Official Gazette. Under the

37. Non-proprietary/chemical names.

rationalised sentence structure, the punishment would vary depending upon whether the quantity of offending material is 'small quantity', 'commercial quantity' or something in-between.

13. It appears from the Statement of Objects and Reasons of the Amending Act of 2001 that the intention of the legislature was to rationalize the sentence structure so as to ensure that while drug traffickers who traffic in significant quantities of drugs are punished with deterrent sentence, the addicts and those who commit less serious offences are sentenced to less severe punishment. Under the rationalised sentence structure, the punishment would vary depending upon the quantity of offending material. Thus, we find it difficult to accept the argument advanced on behalf of the respondent that the rate of purity is irrelevant since any preparation which is more than the commercial quantity of 250 gms. and contains 0.2% of heroin or more would be punishable under section 21(c) of the N.D.P.S. Act, because the intention of the legislature as it appears to us is to levy punishment based on the content of the offending drug in the mixture and not on the weight of the mixture as such. This may be tested on the following rationale. Supposing 4 gms. of heroin is recovered from an accused, it would amount to a small quantity, but when the same 4 gms. is mixed with 50 kgs. of the powered sugar, it would be quantified as a commercial quantity. In the mixture of a narcotic drug or a psychotropic substance with one or more neutral substance, the quantity of the neutral substance/s is not to be taken into consideration while determining the small quantity or commercial quantity of a narcotic drug or psychotropic substance. It is only the actual content by weight of the narcotic drug which is relevant for the purposes of determining whether it would constitute small quantity or commercial quantity. The intention of the legislature for the introduction of the amendment as it appears to us is to punish the people who commit less serious offences with less severe punishment and those who commit grave crimes, such as trafficking in significant quantities, with more severe punishment.

14. In the case of *Ouseph* alias *Thankachan v State of Kerala*, (2004) 4 SCC 446, this Court in para 8 has held as under:

> *The question to be considered by us is whether the psychotropic substance was in a small quantity and if so, whether it was intended for personal consumption. The words small quantity have been specified by the Central Government by the notification dated 23-7-1996. Learned counsel for the State has brought to our notice that as per the said notification small quantity has been specified as 1 gram. If so, the quantity recovered from the appellant is far below the limit of small quantity specified in the notification issued by the Central Government. It is admitted that each ampoule contained only 2 ml and each ml contains only .3 mg. This means the total quantity found in the possession of the appellant was only 66 mg. This is less than 1/10th of the limit of small quantity specified under the notification.*

From the aforesaid decision, we find that the Court has taken the quantity of the narcotic drug or psychotropic substance found in the mixture, relevant for the purpose of imposition of punishment.

15. The learned counsel for the respondent placed reliance on the decision of this Court in *Amarsingh Ramjibhai Barot v State of Gujarat*, (2005) 7 SCC 550 : AIR 2005 SC 4248 : 2005 Cr LJ 4521, in support of his contention that the entire material found in possession irrespective of the content of the offending material has to be taken into consideration while imposing the punishment. In *Amarsingh* case (*supra*), two persons, namely, Amarsingh and Danabhai were apprehended. Amarsingh was found carrying a plastic bag which contained a black-coloured liquid substance weighing 920 gms. Similarly, 4.250 kg. of grey-coloured substance was recovered from Danabhai. Samples were sent to the Forensic Science Laboratory (FSL). The FSL report indicated that the sample from Amarsingh was opium as described in the N.D.P.S. Act containing 2.8% anhydride morphine apart from pieces of poppy flowers and the sample relating to Danabhai was reported to be opium as described in the N.D.P.S. Act having 1.2% anhydride morphine and also containing pieces of poppy flowers. Both the accused were charged and tried under sections 15, 17 and 18 read with section 29 of the N.D.P.S. Act. The High Court found that the conviction under sections 17

and 18 read with section 29 of the N.D.P.S. Act was not correct, but convicted Amarsingh under section 21(c) and also under section 21(c) read with section 29 of the N.D.P.S. Act, for individually being in possession of opium and for being jointly, in conspiracy with the other accused. The High Court found the accused possessed of commercial quantity and convicted and sentenced him for 10 years rigorous imprisonment plus fine of Rs. 1 lakh. Being aggrieved, Amarsingh approached this Court. This Court has held in para 14 of the judgment as under:

> *There does not appear to be any acceptable evidence that the black substance found with the appellant was coagulated juice of the opium poppy and any mixture, with or without any neutral material, of the coagulated juice of the opium poppy. FSL has given its opinion that it is opium as described in the N.D.P.S. Act. That is not binding on the court.*

The Court further held that the evidence also does not indicate that the substance recovered from the appellant would fall within the meaning of sub-clauses (a), (b), (c) or (d) of section 2(xvi), but residuary clause (e) would apply and consequently it would amount to opium derivative as all opium derivatives fall within the expression 'manufactured drugs' Thus, the Court arrived at the conclusion that what was recovered from the appellant was manufactured drug and the offence proved against the appellant fell clearly within section 21 of the N.D.P.S. Act for illicit possession of manufactured drug. The Court concluded and held in para 17 as under:

> *In respect of opium derivatives (at S.I. No. 93) in the said notification, 5 grams is specified as small quantity and 250 grams as commercial quantity. The High Court was, therefore, right in finding that the appellant was guilty of unlawful possession of a commercial quantity of a manufactured drug. Consequently, his case would be covered by clause (c) and not clause (a) or (b) of section 21 of the N.D.P.S. Act.*

This Court has, therefore, upheld the imposition of minimum punishment under section 21(c) of 10 years rigorous imprisonment with fine of Rs. 1 lakh.

16. On going through *Amarsingh* case (*supra*), we do not find that the Court was considering the question of mixture of a narcotic drug or psychotropic substance with one or more neutral substance. In fact that was not the issue before the Court. The black-coloured liquid substance was taken as an opium derivative and the FSL report to the effect that it contained 2.8% anhydride morphine was considered only for the purposes of bringing the substance within the sweep of section 2(xvi)(e) as 'opium derivative which requires a minimum 0.2% morphine. The content found of 2.8% anhydride morphine was not at all considered for the purposes of deciding whether the substance recovered was a small or commercial quantity and the Court took into consideration the entire substance as an opium derivative which was not mixed with one or more neutral substance/s.

> ***Thus, Amarsingh case (supra) cannot be taken to be an authority for advancing the proposition made by the learned counsel for the respondent that the entire substance recovered and seized irrespective of the content of the narcotic drug or psychotropic substance in it would be considered for application of section 21 of the N.D.P.S. Act for the purpose of imposition of punishment. We are of the view that when any narcotic drug or psychotropic substance is found mixed with one or more neutral substance/s, for the purpose of imposition of punishment it is the content of the narcotic drug or psychotropic substance which shall be taken into consideration.***

> ***17. In the present case, the narcotic drug which was found in possession of the appellant as per the analyst's report is 60 g. which is more than 5 g., i.e. small quantity, but less than 250 g, i.e., commercial quantity. The quantity of 60 g is lesser than the commercial quantity, but greater than the small quantity and, thus, the appellant would be punishable under section 21(b) of the N.D.P.S. Act. Further, it is evident that the appellant is merely a carrier and is not a kingpin.***

18. In these circumstances, the ends of justice would be sub served if we reduce the sentence of the accused-appellant to 6 years rigorous imprisonment with fine of Rs. 20,000 and in default of payment of fine rigorous imprisonment for six months. We order accordingly.

37.24 IDENTITY OF DISMEMBERED HUMAN BODY PARTS[38]

(DNA, Odontology, Superimposition used)

Author's Summary

It is a shocking inhuman brutal murder of a medical student by a senior medical student. The culprit dismembered the body and disposed off the parts at various places. Parts were recovered at the instance of the culprit. Forensics established that the various body parts belong to the same person. DNA of the parents and body parts established the identity of the deceased as that of their son.

4. In the academic year of 1995-96 the respondent-accused was studying in the senior first year course of MBBS and the deceased-Navarasu, son of Dr. P.K. Ponnusamy [PW-1], a retired Vice-Chancellor of Madras University, was studying in the junior first year course of MBBS in Raja Muthiah Medical College, Annamalai University, Annamalai Nagar. The respondent was staying in room No. 319 of KRM Hostel and the deceased was staying in room No. 95 in E.1 Malligai Hostel belonging to the same medical college campus. PW-1 returned from his foreign trip on 7-11-1996 and was waiting for the arrival of his son-Navarasu from college to celebrate Diwali which in that relevant year fell on 10-11-1996. When Navarasu did not return home till 9-11-1996, PW-1 started enquiring from the friends of his son, available at Madras but no information of his whereabouts could be gathered by the father. PW-1 then on 9-11-1996 rang up the university authorities to find out and ascertain the whereabouts of his son. When he was informed that the college authority found his hostel room locked and when it was broken upon, it was found that his belongings along with a small box were lying in the room but he was not available in the room. The college authorities and the father were of the opinion that Navarasu had not left for Diwali to Madras. PW-1 thereafter rushed to the University on 10-11-96 and made a complaint of missing of his son at about 11.30 p.m. on 10-11-96 which was registered as Crime No. 509 of 1996 [Exhibit-P1].

5. While this process was going on and without the knowledge of Annamalai Nagar Police, a torso was recovered at about 8.30 a.m. on 7-11-1996 by G. Boopahty, Inspector of Police, E.5 Pattinapakkam [PW-55], from the PTC Bus Depot at Mandaiveli, Madras based on the information given by Prakash 3[PW-53], conductor of the bus route No. 21G. The said recovered torso was sent for post-mortem after an inquest. The Annamalai Nagar Police after registering the missing report started investigation and during the course of such investigation gathered materials and also received information from various persons including students of the college pointing the guilt towards the accused, who was also found absconding from the college premises from 12-14-11-1996. On 14-11-1996 the accused surrendered himself before the Judicial Magistrate, Mannargudi. The message of his surrender was conveyed to the Annamalai Nagar PS, which got the police custody for five days of the accused from 18.11.1996.

On 19-11-1996 at about 1.30 a.m. the accused gave a confessional statement stating that he has put the severed head of the deceased in the boat-canal within the University campus. Pursuant to the said confession, the head was also recovered. Annamalai Nagar PS on 20-11-1996 asked E5. Pattinapakkam PS for sending the records connected with the torso recovered at Madras on the suspicion that it may belong to the severed head of the deceased-Navarasu, which was recovered at the instance of the accused. Dr. K. Ravindran [PW-66] conducted autopsy/post-mortem of the head at 10.00 a.m. on 21-11-1996. On 22-11-1996 a message was received from Villupuram Control Room which was forwarded to Annamalai Nagar PS which

38. *Inspector of Police, Tamil Nadu v John David,* 2011 AIR SCW 2764.

mentioned that three human bones femur, tibia and fibula have been recovered at 1.30 a.m. on 21-11-1996 from the seashore of Konimedu of Merkanam based on the information given by the concerned Village Administrative Officer-Nagarajan [PW-43]. Post-mortem of the limbs were conducted by Dr. Srinivasan [PW-45] and later limbs were sent to PW-66. PW-66, after examining the severed head, the torso and three human bones above mentioned, found that there are scientific materials to hold that they belong to a single individual and also the fact that they belong to deceased-Navasaru.

The father of the deceased PW-1 and Thandeeswaran [PW-60], nephew of PW-1, also identified and confirmed that the head and torso are of the deceased.

For confirming the said fact, the sample blood of PW-1 and his wife Baby Ponnusamy [mother of Navasaru] was examined by Dr. G.V. Rao [PW-77] at Hyderabad by DNA test. PW-77 compared the tissues taken from the severed head, torso and limbs and on scientific analysis he found that the same gene found in the blood of PW-1 and Baby Ponnusamy were found in the recovered parts of the body and that therefore they should belong to the only missing son of PW-1.

37.25 COURT NO SUPER EXPERT[39] [LANDMARK JUDGMENT]

Author's Summary

This is an unfortunate situation where the trial court substituted his own opinion for that of medico-legal expert. SC depreciated the substitution:

"('court's) *opinion is not only unwarranted but also indicative of lack of appreciation of the evidential value to be attached to expert medical evidence".*

Highlights italicised

Relevant Extracts (verbatim)

The learned-trial Judge in his reasoned judgment has taken the view that there is a fatal flaw in the prosecution case since the medical evidence does not support the case of the prosecution of assault on the deceased by so many persons at the same time in the manner and with the weapons stated. It is pointed out that, P.W. 20 Dr. Sankpal, Medical Officer, Primary Health Centre, Narayangaon who did the post-mortem on the body of deceased stated before the Court that there were in all 26 external injuries on the body of the deceased Namdeo. There were fractures found during the internal examination of the body. The external injuries Nos. 7, 22, 23 and 24 are punctured wounds with lacerated edges and the cause of the death of deceased Namdeo is shock due to rupture of left lung and multiple injuries. The left lung was ruptured apparently due to fractured ribs from 8th to 10th on left side.

The learned trial Judge has noted Dr. Sankpal's opinion that the punctured wounds were caused with hard and blunt object, such as, wooden sticks and iron rods and that Dr. Sankpal has identified the wooden sticks (article No. 44) and iron rod (article No. 42) to be the weapons which could have inflicted the punctured wounds on the body of Namdeo -- and logically.

We are constrained to observe that the learned trial Judge was wrong in substituting the expert opinion of the Medical Officer, by his own and, therefore, his findings to the contrary are unjustified and unwarranted.

Dr. Sankpal, P.W. 20 in his deposition before the Court, in paragraph 6 of his evidence, has opined that Injury Nos. 7, 23 and 25 are punctured wounds with lacerated edges. That these injuries could be caused by the rough end of the iron pipe shown to him. He

39. *Gulam Nurmamad Theim v State of Gujarat,* 2002 Cri LR (SC MAH GUJ) : Guj 757 : 2002 (3) Guj LR 2642 : 2003 Cr LJ 356 (Guj).

has further stated that the said injuries can be caused with the wooden sticks and iron bar shown to him before the Court. Dr. Sankpal further opined that considering the nature and number of injuries the same must have been caused due to several strokes and the injuries are found to have been caused all over the body from head up to toe. *Nothing has been brought in the cross-examination of Dr. Sankpal to discredit his expert opinion that the punctured wounds could have been caused with the wooden sticks and iron rod, namely, articles 44 and 42. In fact, in his cross-examination, Dr. Sankpal has reiterated that the punctured wounds mentioned in column 17 of the notes could have been caused by articles 42 and 44 and in order to inflict such wounds, those articles must have been thrust with sufficient force in the body. That the punctured wound with its rough and lacerated edges could be caused by edges of articles 42 and 44.*

Thus nothing has been brought in the cross-examination to reject the expert opinion of Dr. Sankpal that the punctured wounds were caused by the thrust of wooden sticks and iron rods and that the several injuries on the body of the deceased must have been caused due to several strokes inflicted by the accused with wooden sticks and iron rods. That the puncture wounds were caused by wooden sticks and iron rods and the severe nature of injuries caused by several strokes all over the body from head up to toe of the deceased resulted in the death of Namdeo due to shock and rupture of left lung and multiple injuries have been established beyond doubt.

The conclusion of the learned trial judge based on his personal opinion in the face of expert opinion is not only unwarranted but also indicative of lack of appreciation of the evidential value to be attached of expert medical evidence.

37.26 JUDICIAL ACTIVISM[40]

Author's Summary

It is a case of rape and abduction. The IO failed to do his duty, which is highlighted through italicizing the relevant text s enunciated by the High court and endorsed by the SC. It is fortunate that the activism of the courts saw through the dereliction of duty and convicted the culprit u/s 376 IPC for rape and provided justice to the victim and passed strictures against the errant IO.

Relevant Extracts (Verbatim)

29. We now say something about PW-15, S.I. Bagal, who refused, to register an offence and on whom both the trial court and the High Court have commented, and in our view correctly. The trial court in paragraph 34 of the judgment observed as under:

"It is a pathetic situation, when the citizen is confronted with the dishonest police officer. I am constrained to observe that the investigation done by S.I. Bagal P.W. 15, is not only suspicious but also dishonest and out and out in favour of the accused. I am making this observation with responsibility, I have scrutinized carefully the 3 statements recorded by S.I. Bagal, they are very cryptic and favourable to the accused. He did not care to ascertain the correct age of the victim girl, in a kidnapping and rape case. He did not register an offence against the accused. I fail to understand as to what interrogation of the accused he has done. He has obtained the signature on the statement of PW-4 Pushpa and Eknath and right hand thumb impression on the statement of Smt. Vimal for what reason, I do not understand, on three statements. At least he could have registered the offence for kidnapping after taking extract of birth from the school. If he wanted to ascertain the correct date from her father Pandurang and he was aware that PW-1 Pandurang was in K.E.M. Hospital and he wanted to obtain Hospital record, but he never cared to visit K.E.M. Hospital and to record the statement of Pandurang. He was trying to shift the burden

40. *Vishnu v State of Maharashtra,* AIR 2006 SC 508 : 2005 AIR SCW 6149 :2006 Cr LJ 303 (SC).

on the Senior P.I. Sharma. Merely, he had produced these three statements in a routine manner before P.I. Sharma, on the next day. There is no guarantee that he had faithfully recorded statements of all these three witnesses. The reading of the three statements clearly indicates that those are completely in favour of the accused. The entire conduct of S.I. Bagal in the investigation has a smell of suspicion and dishonesty."

The High Court also observed about the conduct of PW-15, S.I. Bagal as under:

"In the present case, the investigation conducted by S.I. Bagal was completely defective and casual. He has not even registered the offence. The learned trial Judge has observed that the attitude of S.I. Bagal was completely dishonest and partial to the accused. On closer scrutiny of the record, we are inclined to agree with the observations of the learned Judge. We have reason to believe that S.I. Bagal deliberately refused to register the offence in order to help the accused at the costs of the prosecutrix. But despite this deficiency, the prosecution has successfully provided the offence of rape. We have, therefore, no hesitation in confirming the conviction recorded by the trial court under section 376 of the IPC."

30. In the facts and circumstances of this case, the comments made by the trial court and the High Court about the manner in which S.I. Bagal conducted the first investigation are well justified.

37.27 STRICTURES ON PRIOR REPORTS[41]

Author's Summary

It is a straightforward case of forgery. A bank employee got a cheque book issued in the name of a customer and withdrew through cheques over a lakh of rupees. The customer reported the fraud. The bank management found the culprit, proved his depredation through a handwriting expert and dismissed him after holding an inquiry.

In defence the forger said that the report of the expert cannot be used as his expertise is tainted due to strictures. The SC held that prior strictures do not prevent acceptance of reliable evidence.

Highlights italicised

Relevant Extracts (Verbatim)

Order of dismissal from service having been restored by Division Bench of Delhi High Court setting aside the judgment of the learned Single Judge, this appeal has been filed.

Factual background filtering out unnecessary details is as follows:

Appellant (hereinafter referred to as 'the employee') joined services of the Lakshmi Commercial Bank in 1976 as a Clerk. The said bank was merged with Canara Bank (hereinafter referred to as 'the employer') in October, 1985. As a consequence, services of the employee stood transferred to the employer-Bank. He was posted as a Clerk in Deen Dayal Upadhyay Marg, New Delhi Branch and was deputed to work at AIWC extension of the said branch.

One customer of the Bank *i.e.,* S.V. Deshpande, advocate lodged a complaint with the police stating that there has been unauthorized withdrawal of Rs. 1.07 lakhs from his account in the Bank. An internal investigation was also undertaken by the employer in respect of the complaint. Report of the preliminary investigation was submitted and the employee was served with charge-sheet along with imputations of misconduct to the effect that the employee was responsible for the unauthorised withdrawal from the customer's account.

41. *Lalit Popli v Canara Bank,* AIR 2003 SC 1796 : 2003 AIR SCW 1238 : (2003) 3 SCC 583.

Enquiry Officer was appointed to hold the enquiry and along with other witnesses the evidence of Handwriting Expert Mr. V.K. Sakhuja was tendered. The proceedings in the enquiry were concluded on 29-4-1993. Both the parties were asked to submit their written submissions. At this stage the employee filed an application for further cross-examination of an Handwriting Expert. Said prayer was rejected on 10th May, 1993. The Enquiry Officer submitted his report and the employee was also furnished with a copy to make his submissions as regards the findings. The written submissions were submitted on 24th June, 1995. Findings of the Enquiry Officer were recorded. Thereafter order of dismissal was passed.

The Disciplinary Authority concurred with findings of the Enquiry Officer after taking into account the submissions made by the employee. The charge sheet contained the following allegations:

> "On the 11th of May, 1992, a charge-sheet was issued to the petitioner in the following terms:—
>
> Whereas, there are *prima facie* grounds for believing that you have committed gross misconduct, the particulars whereof are given below, this charge-sheet has been drawn up against you and you are required to submit me within 15 days of receipt of this charge-sheet a statement in writing setting forth your defence, if any and showing cause as to why suitable action should not be taken against you.

CHARGE:

You have been working at Canara Bank, DDU Marg, New Delhi Branch since 7-3-1986.

One Mr. S.V. Deshpande, Advocate, Supreme Court of India is maintaining his SB A/c. No. 4272 with AIWC Extn. Counter of DDU Marg, New Delhi Branch. On 23-12-1991 a cheque book authorized to be issued in S.B. A/c. No. 4272 to one Sri Mohinder Kumar on the strength of a purported letter in violation of the laid down procedure of the bank. Thereafter, a total of Rs. 1,07,000 was withdrawn from his account by utilising five cheques out of the abovesaid cheque book, details which are given below:

Date	Cheque No.	Amount
26-12-91	460827	Rs. 15,000
28-12-91	460823	Rs. 15,000
31-12-91	460821	Rs. 15,000
31-12-91	460822	Rs. 14,000
31-12-91	460826	Rs. 50,000

The account-holder has complained/disputed above said withdrawals as well as issuance of the cheque book No. 460821 to 460830. The purported letter on the basis of which the abovesaid cheque book had been issued had also not been found on records. The handwriting expert has confirmed that the signatures appearing on the abovesaid cheque are not that of Mr. S.V. Deshpande, the account-holder and they are forged.

The cheque No. 460826 for Rs. 50,000 was posted by you in the relative ledger on 31-12-1991 though there was a fictitious endorsement on the reverse of the cheque to give creditability to the transaction.

Handwriting expert has opined after examining your handwriting with that of the disputed instruments in question that the signatures of the account-holder appearing on the above said five cheques and the endorsement on the back of the cheque No. 46026 for Rs. 50,000 is in your handwriting.

From the above, it is evident that you by misusing your official position, in collusion with someone else, got the above said cheque book issued in S.B. A/c. No. 4272, utilised

the cheque leaves in question by forging the signature of the account-holder and got the same presented to encash the cheques fraudulently.

By your above said fraudulent acts you have caused damage to the property of the bank thereby committed a gross misconduct within the meaning of Chapter XI, regulation 3, clause (j) of Canara Bank Service Code.

Your above said acts are also prejudicial to the interests of the bank thereby you have committed a gross misconduct within the Meaning of Chapter XI, regulation 3, clause (j) of Canara Bank Service Code.

Your abovesaid acts are also prejudicial to the interests of the bank thereby you have committed a gross misconduct within the meaning of the Chapter XI, regulation 3, clause (m) of Canara Bank Service Code.

An appeal was preferred by the employee before the prescribed appellate authority who rejected the appeal. The employee challenged the findings culminating in his order of dismissal by filing a writ petition before the High Court.

The main plea which was advanced before the learned Single Judge was that the Enquiry Officer should not have rested his decision on the opinion of the Handwriting Expert. The entire case rested on suspicion and there was no material to connect him with the alleged misconduct. Learned Single Judge referring to the evidence recorded during the enquiry proceedings came to hold that the conclusions arrived at by the Enquiry Officer were erroneous and no credence should have been attached to the evidence of V.K. Sakhuja and his evidence is no evidence at all. It was also held that the charges framed by the Bank do not have sustainability in law. These observations came to be made by the learned Single Judge because of some adverse remarks made against V.K. Sakhuja in three cases. The conclusions of learned Single Judge in paragraph 17 so far as relevant read as follows:

> *"The fact that the courts had made very strong stricture against the Handwriting Expert is not disputed. In my view, Mr. Sakhuja is not a person who is competent to speak about the handwriting or fingerprints. His evidence is no evidence at all. Consequently, the charge issued by the bank is not sustainable in law. The findings by the Inquiry Officer against the petitioner are not based on any evidence and, thus, the order passed by the disciplinary authority cannot be sustained, in law there is, no evidence against the petitioner. Thus, the order of the disciplinary authority is wholly illegal, and it cannot be sustained."*

In appeal, the Division Bench observed that the High Court in exercise of the power under article 226 of the Constitution of India, 1950 (in short 'the Constitution') does not act as an appellate authority and, therefore, the learned Single Judge was not justified in interfering with the conclusions arrived at by the disciplinary authority. This judgment of the High Court is under challenge.

Learned counsel appearing for the appellant-employee submitted that there has been denial of fair play. There is no material to connect the appellant with alleged forgery, which was the foundation for the disciplinary action. Report of the Handwriting Expert about whose credibility serious remarks were made has no evidentiary value, and he is not a competent witness and his report which forms the foundation for disciplinary action has to be ignored and if that is kept out of consideration, there is no other material on which the allegations of misconduct could be substantiated. It is pointed out that when the investigation was done initially, a report was submitted by the Forensic Science Laboratory which did not find any material against the employee and others. The employee was also denied an adequate opportunity to submit his reply as regards the enquiry report. The charges related to two transactions. One was posting of the cheque and the other related to forgery. Report of the Handwriting Expert is full of inconsistencies and the conclusion about similarity in handwriting in the disputed document and the admitted signatures has been drawn erroneously. To prove his innocence the employee had requested the authorities to hand over the enquiry to the Central Bureau of Investigation. This request was made as the employee was convinced that the authorities were bent upon removing him from service for union activities. Further, request was made for being represented by an advocate which

was turned down. The employee had requested for supply of certain documents which were not accepted to causing thereby prejudice.

Learned counsel for the respondents on the other hand submitted that the Division Bench rightly considered the scope and ambit of judicial review in the matter of disciplinary proceedings. The stand that the Handwriting Expert's report cannot be accepted without further corroboration is not the correct proposition in law. Denial of the representation by an advocate was also justified because the presenting officer was not an advocate or a person with a law background. The only area of dispute related to acceptability of the Handwriting Expert's report. The employee who claimed to be a trade union activist is well-versed with various aspects relating to service jurisprudence, has cross-examined at length and quite effectively the management witnesses. Therefore, there is no substance in the plea that there was prejudice by refusal of permission to be represented by an advocate. It was further submitted that no argument was advanced before the High Court (either before learned Single Judge or the Division Bench) regarding prejudice. It is also pointed out that the employee himself held accepted that he committed careless mistakes, but took the plea that there was no criminal intent. The authorities have analysed the job requirements of the post which the employee held and discussed at great length as to how the requisite care and caution were not exercised. A bare look at the endorsement on the back side of the cheque would have aroused suspicion. The plea that many transactions took place that day is clearly without substance because an employee of the bank is required to be vigilant and any abnormality should have been noticed. The customer was an advocate and he could not have mis-spelt the word 'signature' as appears on the reverse side of the cheque in question in the endorsement. There was an unusual endorsement and withdrawal of Rs. 50,000 by a bearer cheque. The unusual features should have aroused suspicion. That being so, the authorities were justified in drawing adverse remarks. The report of the Handwriting Expert is clear and cogent and has clearly spelt out the areas of similarities in the disputed document and the admitted writings to highlight as to how employee was the author of forgery.

To start with the approach of the learned Single Judge as regards evidence of V.K. Sakhuja is clearly erroneous. Even if there were adverse remarks (which we find related to 1958-59) that did not affect the credibility of his evidence to treat it as totally irrelevant and to be no evidence in the eye of law. What was required was a careful analysis of evidence, if it was brought to the notice of the authorities that his evidence has been doubted in the past. Nothing could be shown to us as to how the report in this particular case suffers from any infirmity. There is no finding recorded by the learned Single Judge to that effect. On that score alone, the Division Bench was justified in upsetting the learned Single Judge's decision.

Sections 45 and 73 of the Indian Evidence Act, 1872 (in short 'The Evidence Act') deal with opinion of experts and comparison of signature, writing or seal with others admitted or proved. Section 45 itself provides that the opinions are relevant facts. It is a general rule that the opinion of witnesses possessing peculiar skill is admissible. There was no challenge to the expertise of V.K. Sakhuja. He deposed to have testified in about ten thousand cases relating to disputed documents. Though the employee highlighted certain adverse remarks, it cannot be lost sight of that they were about four decades back. But we need not go into that aspect in detail as no infirmity in the report acted upon by the authority in the present case was noticed or could be pointed out.

It is to be noted that under sections 45 and 47 of the Evidence Act, the court has to take a view on the opinion of others, whereas under section 73 of the said Act, the court by its own comparison of writings can form its opinion. Evidence of the identity of handwriting is dealt with in three sections of the Evidence Act. They are sections 45, 47 and 73. Both under sections 45 and 47 the evidence is an opinion. In the former case it is by a scientific comparison and in the latter on the basis of familiarity resulting from frequent observations and experiences. In both the cases, the court is required to satisfy itself by such means as are open to conclude that the opinion may be acted upon. Irrespective of an opinion of the Handwriting Expert, the court can compare the admitted writing with disputed writing and come to its own independent conclusion. Such exercise of comparison is permissible

under section 73 of the Evidence Act. Ordinarily, sections 45 and 73 are complementary to each other. Evidence of Handwriting Expert need not be invariably corroborated. It is for the court to decide whether to accept such an uncorroborated evidence or not. It is clear that even when experts' evidence is not there, court has the power to compare the writings and decide the matter. [See *Murarilal v State of Madhya Pradesh,* (1980) 1 SCC 704 : AIR 1980 SC 531 : 1980 Cr LJ 396 : (1980) 2 SCR 249.]

In the instant case, the Enquiry Officer and the Disciplinary Authority took pains to carefully consider the Handwriting Expert's report and also looked at the documents to arrive at their own conclusions.

Great emphasis was laid on the Forensic Science Laboratory's report to say that the Handwriting Expert's report is not worthy of acceptance. We have looked at the report of the Forensic Science Laboratory. It only says that no definite opinion can be formed. That itself is an indication that a clean chit was not given as claimed by the employee.

It is fairly well-settled that the approach and objective in criminal proceedings and the disciplinary proceedings are altogether distinct and different. In the disciplinary proceedings the preliminary question is whether the employee is guilty of such conduct as would merit action against him whereas in criminal proceedings the question is whether the offences registered against him are established and if established what sentence should be imposed upon him. The standard of proof, the mode of enquiry and the rules governing the enquiry and trial are conceptually different.

See *State of Rajasthan v B.K. Meena,* (1996) 6 SCC 417 : 1996 AIR SCW 4160 : AIR 1997 SC 13 : 1996 (3) SCJ 582. In case of disciplinary enquiry the technical rules of evidence have no application. The doctrine of "proof beyond doubt" has no application. The preponderance of probabilities and some material or record are necessary to arrive at the conclusion whether or not the delinquent has committed misconduct.

While exercising jurisdiction under article 226 of the Constitution the High Court does not act as an appellate authority. Its jurisdiction is circumscribed by limits of judicial review to correct errors of law or procedural errors leading to manifest injustice or violation of principles of natural justice. Judicial review is not akin to adjudication of the case on merits as an Appellate Authority.

In *B.C. Chaturvedi v Union of India,* (1995) 6 SCC 749 : AIR 1996 SC 484 : 1995 AIR SCW 4374 : JT 1995 (8) SC 65, the scope of judicial review was indicated by stating that review by the court is of decision-making process and where the findings of the disciplinary authority are based on some evidence, the court or the Tribunal cannot re-appreciate the evidence and substitute its own finding.

As observed in *R.S. Saini v State of Punjab,* (1999) 8 SCC 90 : AIR 1999 SC 3579 : 1999 AIR SCW 3587 : (1999) 5 SCALE 427 in paragraphs 16 and 17 the scope of interference is rather limited and has to be exercised within the circumscribed limits. It was noted as follows:

> Before adverting to the first contention of the appellant regarding want of material to establish the charge, and of non-application of mind, we will have to bear in mind the rule that the court while exercising writ jurisdiction will not reverse a finding of the enduring authority on the ground that the evidence adduced before it is insufficient. If there is some evidence to reasonably support the conclusion of the inquiring authority, it is not the function of the court to review the evidence and to arrive at its own independent finding. The inquiring authority is the sole judge of the fact so long as there is some legal evidence to substantiate the finding and the adequacy or reliability of the evidence is not a matter which can be permitted to be canvassed before the court in writ proceedings.

A narration of the charges and the reasons of the inquiring authority for accepting the charges, as seen from the records, shows that the inquiring has based its conclusions on materials available on record after considering the defence put forth by the appellant and these decisions, in our opinion, have taken in a reasonable manner and objectively. The conclusion arrived at by the inquiring authority cannot be termed as either being

perverse or not based on any material nor is it a case where there has been any non-application of mind on the part of the inquiring authority. Likewise the High Court has looked into the material based on which the enquiry officer has come to the conclusion, within the limited scope available to it under article 226 of the Constitution and we do not find any fault with the finding of the High Court in this regard."

As noted above, the employee accepted that there was some lapse on his part but he pleaded lack of criminal intent. A bank employee deals with public money. The nature of his work demands vigilance with the inbuilt requirement to act carefully. Any carelessness invites action.

As has been rightly submitted by learned counsel for the respondents-Bank, even to the naked eye the mistake in spelling of "signature" are visible and should not have escaped the eyes of a bank employee who is supposed to be trained and equipped to notice the similarities highlighted by the Handwriting expert in the disputed document and the admitted signatures of the employee to show how the similarly is visible and even any layman can notice the similarity. These were a factual conclusion.

Considering the limited scope of judicial review, the Division Bench was right in upholding the order of dismissal by setting aside the learned Single Judge's order by which interference was made with it. We find no reason to differ from the conclusion of the Division Bench. The appeal is without merit and is dismissed accordingly.

37.28 NOETIC SCIENCES: EMERGING FORENSICS[42]

Author's Summary

This is an unfortunate negative landmark SC judgment on noetic sciences, namely, *polygraph/ /narco-analysis/the Brain Electrical Activation Profile (BEAP)* tests. It disallowed their effective use as evidence in courts but allowed their use in investigation only, subject to the consent of the accused.

The ruling, thereby, tacitly allowed the investigators to use their traditional III Degree modes in interrogation. It, thus, promote inhuman treatment of the suspect under interrogation.

The SC has ruled that for voluntary use of these scientific tests, the guideline provided by the Human Right Commission must be followed scrupulously.

Highlights italicised

Relevant Extracts (Verbatim)

1. The legal questions in this batch of criminal appeals relate to the involuntary administration of certain scientific techniques, namely ***narcoanalysis, polygraph examination and the Brain Electrical Activation Profile (BEAP)*** test for the purpose of improving investigation efforts in criminal cases. This issue has received considerable attention since it involves tensions between the desirability of efficient investigation and the preservation of individual liberties. Ordinarily the judicial task is that of evaluating the rival contentions in order to arrive at a sound conclusion. However, the present case is not an ordinary dispute between private parties. It raises pertinent questions about the meaning and scope of fundamental rights which are available to all citizens. Therefore, we must examine the implications of permitting the use of the impugned techniques in a variety of settings.

2. Objections have been raised in respect of instances where individuals who are the accused, suspects or witnesses in an investigation have been subjected to these tests without

42. *Smt. Selvi v State of Karnataka*, AIR 2010 SC 1974.

their consent. Such measures have been defended by citing the importance of extracting information which could help the investigating agencies to prevent criminal activities in the future as well as in circumstances where it is difficult to gather evidence through ordinary means. In some of the impugned judgments, reliance has been placed on certain provisions of the Code of Criminal Procedure, 1973 and the Indian Evidence Act, 1872 to refer back to the responsibilities placed on citizens to fully co-operate with investigation agencies. It has also been urged that administering these techniques does not cause any bodily harm and that the extracted information will be used only for strengthening investigation efforts and will not be admitted as evidence during the trial stage. The assertion is that improvements in fact-finding during the investigation stage will consequently help to increase the rate of prosecution as well as the rate of acquittal. Yet another line of reasoning is that these scientific techniques are a softer alternative to the regrettable and allegedly widespread use of 'third degree methods' by investigators.

3. *The involuntary administration of the impugned techniques prompts questions about the protective scope of the 'right against self-incrimination' which finds place in Article 20(3) of our Constitution. In one of the impugned judgments, it has been held that the information extracted through methods such as 'polygraph examination' and the 'Brain Electrical Activation Profile (BEAP) test' cannot be equated with 'testimonial compulsion' because the test subject is not required to give verbal answers, thereby falling outside the protective scope of Article 20(3). It was further ruled that the verbal revelations made during a narcoanalysis test do not attract the bar of article 20(3) since the inculpatory or exculpatory nature of these revelations is not known at the time of conducting the test.*

To address these questions among others, it is necessary to inquire into the historical origins and rationale behind the 'right against self-incrimination'. The principal questions are whether this right extends to the investigation stage and whether the test results are of a 'testimonial' character, thereby attracting the protection of article 20(3). Furthermore, we must examine whether relying on the test results or materials discovered with the help of the same creates a reasonable likelihood of incrimination for the test subject.

4. We must also deal with arguments invoking the guarantee of 'substantive due process' which is part and parcel of the idea of 'personal liberty' protected by article 21 of the Constitution. The first question in this regard is whether the provisions in the Code of Criminal Procedure, 1973 that provide for 'medical examination' during the course of an investigation can be read expansively to include the impugned techniques, even though the latter are not explicitly enumerated. To answer this question, it will be necessary to discuss the principles governing the interpretation of statutes in light of scientific advancements. Questions have also been raised with respect to the professional ethics of medical personnel involved in the administration of these techniques. Furthermore, article 21 has been judicially expanded to include a 'right against cruel, inhuman or degrading treatment', which requires us to determine whether the involuntary administration of the impugned techniques violates this right whose scope corresponds with evolving international human rights norms. We must also consider contentions that have invoked the test subject's 'right to privacy', both in a physical and mental sense.

5. The scientific validity of the impugned techniques has been questioned and it is argued that their results are not entirely reliable. For instance, the narco-analysis technique involves the intravenous administration of sodium pentothal, a drug which lowers inhibitions on part of the subject and induces the person to talk freely. However, empirical studies suggest that the drug-induced revelations need not necessarily be true. Polygraph examination and the BEAP test are methods which serve the respective purposes of lie-detection and gauging the subject's familiarity with information related to the crime.

These techniques are essentially confirmatory in nature, wherein inferences are drawn from the physiological responses of the subject. However, the reliability of these methods has been repeatedly questioned in empirical studies.

In the context of criminal cases, the reliability of scientific evidence bears a causal link with several dimensions of the right to a fair trial such as the requisite standard of proving guilt beyond reasonable doubt.

* * * * *

7. At this stage, it will be useful to frame the questions of law and outline the relevant sub-questions in the following manner:

I. Whether the involuntary administration of the impugned techniques violates the 'right against self-incrimination' enumerated in article 20(3) of the Constitution?

I-A. Whether the investigative use of the impugned techniques creates a likelihood of incrimination for the subject?

I-B. Whether the results derived from the impugned techniques amount to 'testimonial compulsion' thereby attracting the bar of article 20(3)?

II. Whether the involuntary administration of the impugned techniques is a reasonable restriction on 'personal liberty' as understood in the context of article 21 of the Constitution?

It was unanimously held that the 'general acceptance' standard articulated in Frye (supra.) had since been displaced by the enactment of the Federal Rules of Evidence in 1975, wherein rule 702 governed the admissibility of expert opinion testimony that was based on scientific findings. This rule provided that:

> *If scientific, technical, or other specialised knowledge will assist the trier of fact to understand the evidence or to determine a fact in issue, a witness qualified as an expert by knowledge, skill, experience, training, or education, may testify thereto in the form of an opinion or otherwise.*

23. It was held that the trial court should have evaluated the scientific evidence as per rule 702 of the Federal Rules of Evidence which mandates an inquiry into the relevance as well as the reliability of the scientific technique in question. The majority opinion (Blackmun, J.) noted that the trial judge's step should be a preliminary assessment of whether the testimony's underlying reasoning or methodology is scientifically valid and whether it can be properly applied to the facts in issue. Several other considerations will be applicable, such as:

1. whether the theory or technique in question can be and has been tested
2. whether it has been subjected to peer review and publication
3. its known or potential error rate
4. the existence and maintenance of standards controlling its operation
5. whether it has attracted widespread acceptance within the scientific community

24. It was further observed that such an inquiry should be a flexible one, and its focus must be solely on principles and methodology, not on the conclusions that they generate. It was reasoned that instead of the wholesale exclusion of scientific evidence on account of the high threshold of proving "general acceptance in the particular field," the same could be admitted and then challenged through conventional methods such as cross-examination, presentation of contrary evidence and careful instructions to juries about the burden of proof. In this regard, the trial judge is expected to perform a 'gate-keeping' role to decide on the admission of expert testimony based on scientific techniques. It should also be kept in mind that Rule 403 of the Federal Rules of Evidence, 1975 empowers a trial judge to exclude any form of evidence if it is found that its probative value will be outweighed by its prejudicial effect.

* * * * *

Conclusion

221. *In our considered opinion, the compulsory administration of the impugned techniques*[43] *violates the 'right against self-incrimination'. This is because the underlying rationale of the*

43. Polygraph Test, Narco-analysis, Brain Electrical Activation Profile.

said right is to ensure the reliability as well as voluntariness of statements that are admitted as evidence. This Court has recognised that the protective scope of article 20(3) extends to the investigative stage in criminal cases and when read with section 161(2) of the Code of Criminal Procedure, 1973 it protects accused persons, suspects as well as witnesses who are examined during an investigation. The test results cannot be admitted in evidence if they have been obtained through the use of compulsion. Article 20(3) protects an individual's choice between speaking and remaining silent, irrespective of whether the subsequent testimony proves to be inculpatory or exculpatory. Article 20(3) aims to prevent the forcible 'conveyance of personal knowledge that is relevant to the facts in issue'. The results obtained from each of the impugned tests bear a 'testimonial' character and they cannot be categorized as material evidence.

222. We are also of the view that forcing an individual to undergo any of the impugned techniques violates the standard of 'substantive due process' which is required for restraining personal liberty. Such a violation will occur irrespective of whether these techniques are forcibly administered during the course of an investigation or for any other purpose since the test results could also expose a person to adverse consequences of a non-penal nature. The impugned techniques cannot be read into the statutory provisions which enable medical examination during investigation in criminal cases, *i.e.,* the *Explanation* to sections 53, 53A and 54 of the Code of Criminal Procedure, 1973. Such an expansive interpretation is not feasible in light of the rule of '*ejusdem generis*' and the considerations which govern the interpretation of statutes in relation to scientific advancements.

We have also elaborated how the compulsory administration of any of these techniques is an unjustified intrusion into the mental privacy of an individual. It would also amount to 'cruel, inhuman or degrading treatment' with regard to the language of evolving international human rights norms. Furthermore, placing reliance on the results gathered from these techniques comes into conflict with the "right to fair trial". Invocations of a compelling public interest cannot justify the dilution of constitutional rights such as the 'right against self-incrimination'.

223. In light of these conclusions, we hold that no individual should be forcibly subjected to any of the techniques in question, whether in the context of investigation in criminal cases or otherwise. Doing so would amount to an unwarranted intrusion into personal liberty. However, we do leave room for the voluntary administration of the impugned techniques in the context of criminal justice, provided that certain safeguards are in place. Even when the subject has given consent to undergo any of these tests, the test results by themselves cannot be admitted as evidence because the subject does not exercise conscious control over the responses during the administration of the test. However, any information or material that is subsequently discovered with the help of voluntary administered test results can be admitted, in accordance with section 27 of the Evidence Act, 1872.

The National Human Rights Commission had published 'Guidelines for the Administration of Polygraph Test (Lie Detector Test) on an Accused' in 2000. These guidelines should be strictly adhered to and similar safeguards should be adopted for conducting the 'Narcoanalysis technique' and the 'Brain Electrical Activation Profile' test.

The text of these guidelines has been reproduced below:

(i) No Lie Detector Tests should be administered except on the basis of the consent of the accused. An option should be given to the accused whether he wishes to avail such test.

(ii) If the accused volunteers for a Lie Detector Test, he should be given access to a lawyer and the physical, emotional and legal implication of such a test should be explained to him by the police and his lawyer.

(iii) The consent should be recorded before a Judicial Magistrate.

(iv) During the hearing before the Magistrate, the person alleged to have agreed should be duly represented by a lawyer.

(v) At the hearing, the person in question should also be told in clear terms that the statement that is made shall not be a "confessional" statement to the Magistrate but will have the status of a statement made to the police.

(vi) The Magistrate shall consider all factors relating to the detention including the length of detention and the nature of the interrogation.

(vii) The actual recording of the Lie Detector Test shall be done by an independent agency (such as a hospital) and conducted in the presence of a lawyer.

(viii) A full medical and factual narration of the manner of the information received must be taken on record.

37.29 BRAIN MAPPING[44]

Author's Summary

A.K. Telgi, a master forger, committed forgery and fraud on an unprecedented scale. He looted thousands of crores of rupees by producing and selling fake stamp paper. He was convicted for the crime; though the SC did not accept the new type of evidence (brain printing) produced by the prosecution dubbing it was vague and not well established.

Highlights italicised

Relevant Extracts (Verbatim)

III. According to the prosecution, following circumstance could not be explained by the applicant.

(a) The fact that he had closed door meeting with A.K. Telgi in isolation between himself and A.K.L. Telgi only to the exclusion of other high ranking officers (Statement of ACP Supriya Patil at Page No. 11912. DCP (HQ) Koregaonkar at Page No. 11898 and DCP Jay Jadhav at Page No. 111940).

(b) The applicant knew A.K.L. Telgi even when he was at Mumbai earlier is also apparent from the statement of DCP Vasant Koregaonkar (Page No. 11898).

(c) Brain Maping (P. 300) of AKL Telgi, shows that he had given positive responses to the question relating to payment made to the applicant, favour shown by the applicant in Pune cases and facilities provided in Mumbai custody by the applicant (Page No. 12960 to 12963)."

13. The plea taken by the Appellant herein about his innocence was rejected by the High Court.

87. *Apart from the fact that nothing has been brought on record to show as to how far a report of brain mapping test can be relied upon, the report appears to be vague. It appears, the Respondents themselves did not want to put much reliance on the said report.*

88. Furthermore, the admissibility of a result of a scientific test will depend upon its authenticity. Whether the brain mapping test is so developed that the report will have a probative value so as to enable a court to place reliance thereupon, is a matter which would require further consideration, if and when the materials in support thereof are placed before the Court.

89. In *Frye v United States,* [293 F 1013 (DC Cir) (1923)], the principles to determine the strength of any investigation to make it admissible were stated in the following terms:

> "Just when a scientific principle or discovery crosses the line between the experimental and demonstrable stages is difficult to define. Somewhere in the twilight zone the evidential force must be recognized, and while the Courts will go a long way in admitting the expert testimony deduced from a well-recognized scientific principle or discovery, the thing from which the deduction is made must be sufficiently established to have gained general acceptance in the particular field in which it belongs.

90. *Frye* (supra), however, was rendered at a time when the technology, the polygraph test, was in its initial stage and was used in few laboratories. The guidelines issued therein posed a threat of lack of judicial adaptation of the new developments and ignored the reliability on a particular piece of evidence.

44. *Ranjitsing Brahmajeetsing Sharma v State of Maharashtra*, AIR 2005 SC 2277 : 2005 AIR SCW 2215 : 2005 Cr LJ 2533.
